**Abstract.** Here we describe the first version of a new, analytical early diagenetic model resolving organic matter cycling and associated biogeochemical dynamics in marine sediments called OMEN-SED (Organic Matter ENabled SEDiment model). Most biogeochemical cycles and reactions in the surface sediments can be related either directly or indirectly to the degradation of organic matter.

- 5 Despite its fundamental importance, an appropriate Earth System model of the coupled atmosphere-ocean-sediment system which is able to model all relevant processes and feedbacks over geological time-scales currently does not exist. The major problem is the high computational cost of simulating the essential redox reactions in marine sediments which are important to calculate burial of organic matter and benthic recycling fluxes of chemical compounds. In most Earth System models sediment-  
10 water dynamics are either neglected or treated in a very simplistic way. To provide a more realistic description of organic matter degradation and nutrient cycles in marine sediments we have developed OMEN-SED, a new, one-dimensional, numerically efficient reactive transport model. OMEN-SED is the first analytical model to explicitly describe organic matter cycling as well as associated dynamics of the most important terminal electron acceptors (i.e. O<sub>2</sub>, NO<sub>3</sub>, SO<sub>4</sub>), related reduced substances  
15 (NH<sub>4</sub>, H<sub>2</sub>S), the full suite of secondary-redox reactions, macronutrients (PO<sub>4</sub>) and associated pore water quantities (ALK, DIC). To represent a redox-dependent sedimentary P cycle we consider the formation and burial of Fe-bound P and authigenic Ca-P minerals. Thus, OMEN-SED captures most of the features of a complex, numerical diagenetic model, however, its computational efficiency allows the coupling to global Earth System models and therefore the investigation of coupled global  
20 biogeochemical dynamics over different timescales. This paper provides a detailed description of

the new sediment model, **tested with observations, SA and global observations** and describes it's coupling to the Earth System model cGENIE.

## 1 Introduction

**DH:** Will delete the sub-headings!

### 60 Role of marine sediments for climate and global biogeochemical cycles:

Marine surface sediments are key components in the Earth system. They host the largest carbon reservoir within the surficial Earth system, provide the only long term sink for atmospheric CO<sub>2</sub>, recycle nutrients and represent the most important geochemical archive used for deciphering past changes in biogeochemical cycles and climate (e.g. Berner, 1991; Archer and Maier-Reimer, 1994; Ridgwell and Zeebe, 2005; Arndt et al., 2013). Physical and chemical processes in sediments (i.e. diagenetic processes) depend on the water column and vice versa: Diagenesis is mainly donor controlled, as it is fuelled by the external supply of solid material (e.g. organic matter, calcium carbonate, opal) from the water column and is affected by overlying bottom water concentrations of solutes. At the same time, sediments impact the water column directly either by short- and long-term storage of deposited material or diagenesis transforms deposited material and returns some of the resulting products (e.g. nutrients, DIC) to the bottom waters. This so-called benthic-pelagic coupling is essential for understanding global biogeochemical cycles and climate (e.g. Archer and Maier-Reimer, 1994; Archer et al., 2000; Soetaert et al., 2000; Mackenzie, 2005).

75 Biological primary production of organic matter (OM, CH<sub>2</sub>O in equation R1) and the reverse process of degradation can be written in a greatly simplified reaction as:

On geological timescales production of OM is generally greater than degradation which results in some organic matter being buried in marine sediments and oxygen accumulating in the atmosphere. Thus burial of OM leads to net oxygen input to, and CO<sub>2</sub> removal from the atmosphere (Berner, 2004). On shorter timescales, the upper few meters of the sediments (i.e. early diagenesis) are specifically important as it is decided here if a substance is recycled to the water column or buried for a longer period of time in the deeper sediments (Hensen et al., 2006). Most biogeochemical cycles and reactions in this part of marine sediments can be related either directly or indirectly to the degradation of organic matter (e.g Boudreau and Ruddick, 1991; Arndt et al., 2013). Organic matter degradation releases metabolic CO<sub>2</sub> to the pore water, causing it to have a lower pH and provoking the dissolution of CaCO<sub>3</sub> (Emerson and Bender, 1981). Oxygen and nitrate for instance, the most powerful electron acceptors, are consumed in the course of the degradation of organic matter, resulting in the release of ammonium and phosphorus to the pore water. As such, degradation of OM in the sediments can profoundly affect the oxygen and nutrient inventory of the ocean and thus primary productivity (Van Cappellen and Ingall, 1994; Lenton and Watson, 2000).

Nutrient recycling from marine sediments has been suggested to play a key role for climate and ocean biogeochemistry for different events during Earth history. For example, feedbacks between phosphorus storage and erosion from shelf sediments and marine productivity have been hypothesised to play an important role for glacial/interglacial atmospheric CO<sub>2</sub> changes (Broecker, 1982;

95 Ruttenberg, 1993). Furthermore, nutrient recycling from anoxic sediments has been invoked to ex-  
plain the occurrence of more extreme events in Earth history, for instance Oceanic Anoxic Events  
(OAEs, e.g. Mort et al., 2007; Tsandev and Slomp, 2009). OAEs represent severe disturbances of the  
global carbon, oxygen and nutrient cycles of the ocean and are usually characterized by widespread  
bottom water anoxia and photic zone euxinia (Jenkyns, 2010). One way to explain the genesis and  
100 persistence of OAEs is increased oxygen demand due to enhanced primary productivity. Increased  
nutrient inputs to fuel primary productivity may have come from marine sediments as the burial  
efficiency of phosphorus declines when bottom waters become anoxic (Ingall and Jahnke, 1994;  
Van Cappellen and Ingall, 1994). The recovery from OAE like conditions is thought to involve the  
permanent removal of excess CO<sub>2</sub> from the atmosphere and ocean by burying carbon in the form  
105 of organic matter in marine sediments (e.g. Arthur et al., 1988; Jarvis et al., 2011), which is consis-  
tent with the geological record of widespread black shale formation (Stein et al., 1986). However,  
the overall amount, exact timing and the rate of organic matter burial remain a topic of an ongoing  
debate.

#### **Diagenetic Models:**

110 Therefore, globally quantifying the burial and degradation of organic matter in marine sediments and  
related biogeochemical dynamics is important for understanding climate and the cycling of many  
chemical elements on various timescales. Such studies and quantifications are possible through the  
application of idealised mathematical representations of diagenesis, or so-called diagenetic models  
(see e.g. Berner, 1980; Boudreau, 1997). The number of research questions that can be addressed  
115 with diagenetic models is infinite and a plethora of different approaches have been developed, mainly  
following two distinct directions (Arndt et al., 2013).

First, state-of-the art vertically resolved numerical models simulating the entire suite of essen-  
tial coupled redox and equilibrium reactions within marine sediments (e.g. BRNS, Aguilera et al.,  
2005; CANDI, Boudreau, 1996; MEDIA, Meysman et al., 2003; STEADYSED, Van Cappellen and  
120 Wang, 1996). These “complete”, non-steady-state models, thus resolve the resulting characteristic  
redox-zonation of marine sediments through explicitly including oxic OM degradation, denitrification,  
oxidation by manganese and iron (hydr)oxides, sulfate reduction and methanogenesis as well  
as the reoxidation of reduced byproducts (i.e. NH<sub>4</sub>, Mn<sup>2+</sup>, Fe<sup>2+</sup>, H<sub>2</sub>S, CH<sub>4</sub>). Furthermore, they in-  
corporate various mineral dissolution and precipitation reactions, as well as fast equilibrium sorption  
125 processes for example of NH<sub>4</sub>, PO<sub>4</sub> and metal ions (i.e. Mn<sup>2+</sup>, Fe<sup>2+</sup> and Mg<sup>2+</sup>, compare Van Cap-  
pellen and Wang, 1996; Meysman et al., 2003). Modelled, depth-dependent, transport processes usu-  
ally comprise advection, diffusion, bioturbation and bio-irrigation. This group of diagenetic models  
generally uses a so-called multi-G approach (Jørgensen, 1978; Berner, 1980), thus dividing the bulk  
130 organic matter pool into a number of compound classes that are characterised by different degrad-  
abilities  $k_i$ , which are generally dependent on the type and concentration of the specific terminal  
electron acceptor (TEA). These complex models have a great potential for quantifying OM degra-

dation dynamics for sites where enough observations are available to constrain its model parameters (see e.g. Boudreau et al., 1998; Wang and Van Cappellen, 1996; Thullner et al., 2009, for applications). However, due to the high degree of coupled processes and depth-varying parameters the 135 diagenetic equation needs to be solved numerically, thus resulting in a very high computational demand and consequently rendering their application in an Earth system model framework prohibitive. Additionally, their global applicability is limited by the restricted transferability of model parameters from one site to the global scale (Arndt et al., 2013).

The second group of models solves the diagenetic equation analytically or semi-analytically, thus 140 providing an alternative and computational more efficient approach. However, finding an analytical solution, especially when complex reaction networks are to be considered, is not straightforward and generally requires the assumption of steady state. The complexity of the reaction network can be reduced by dividing the sediment column into distinct zones and accounting for the most pertinent biogeochemical processes within each zone, thus increasing the likelihood of finding an analytical 145 solution. In general, analytical diagenetic models are less sophisticated and comprehensive than numerical models and are used for the coupling to global ESMs (e.g. HAMOCC and NorESM use the model of Heinze et al. (1999)) or box models (e.g. DCESS, Shaffer et al., 2008 or MBM using MEDUSA, Munhoven, 2007). These analytic or semi-analytical models account for the most important transport processes (i.e advection, bioturbation and molecular diffusion) through basic 150 parametrizations and include fewer biogeochemical reactions which are generally restricted to the upper, bioturbated 10 cm of the sediments. They assume that the sedimentary organic matter pool is composed of just a single compound class which is either degraded with a globally invariant degradation rate constant (Munhoven, 2007) or a fixed rate constant depending on local oxygen concentrations (Shaffer et al., 2008; Palastanga et al., 2011). Pore water tracers explicitly represented in 155 DCESS (Shaffer et al., 2008) and the HAMOCC model of Heinze et al. (1999) and Palastanga et al. (2011) are restricted to DIC, TA, PO<sub>4</sub> and O<sub>2</sub>. The MEDUSA model (Munhoven, 2007) considers CO<sub>2</sub>, HCO<sub>3</sub><sup>-</sup>, CO<sub>3</sub><sup>2-</sup> and O<sub>2</sub>. Other species produced or consumed during OM degradation are neglected. Thus, with oxygen being the only TEA explicitly modelled the influence of reduced species is only implicitly included in the boundary conditions for O<sub>2</sub>. A newer versions of the HAMOCC 160 model, being a notable exception, as Ilyina et al. (2013) include NO<sub>3</sub> and denitrification explicitly. Furthermore, the version of Palastanga et al. (2011) represents an redox-dependent explicit sedimentary phosphorus cycle. Yet, secondary redox reactions involving reduced substances or sorption processes are not included in any of the discussed models.

#### **How are sediments resolved in Earth system models:**

165 Earth system models generally track the biogeochemical dynamics of organic and inorganic carbon, essential nutrients (nitrogen, phosphorus) and oxygen with the aim of investigating the evolution of the ocean's redox structure and carbonate system and its feedbacks on global climate. This general aim thus defines a minimum set of state variables and reaction processes that need to be resolved

for an efficient representation of the benthic-pelagic coupling in Earth system models. A suitable  
170 sediment model has to provide a robust quantification of organic (and inorganic) carbon burial fluxes,  
as well as benthic uptake/return fluxes of oxygen, growth-limiting nutrients and reduced species. As  
a consequence, the reaction network must account for the most important primary and secondary  
redox reactions, equilibrium reactions, mineral precipitation/dissolution and adsorption/desorption,  
resulting in a complex set of coupled reaction-transport equations.

175 Even though there are more appropriate sediment representations, in most current ESMs sediment-  
water dynamics are either neglected or treated in a very simplistic way (Soetaert et al., 2000; Hülse  
et al., 2017). Most Earth system Models of Intermediate Complexity (EMICs) and also some of  
the higher resolution global carbon cycle models represent the sediment-water interface either as a  
reflective or a conservative/semi-reflective boundary (Hülse et al., 2017). Thus, all particulate ma-  
180 terial deposited on the seafloor is either instantaneously consumed (reflective boundary), or a fixed  
fraction is buried in the sediments (conservative/semi-reflective boundary). Both highly simplified  
approaches furthermore completely neglect the exchange of solute species through the sediment-  
water interface and, therefore, cannot resolve the complex benthic-pelagic coupling. However, due  
to their computational efficiency, both representations are often used in global biogeochemical mod-  
185 els (e.g. Najjar et al., 2007; Ridgwell et al., 2007; Goosse et al., 2010). A superior approach is  
the vertically integrated dynamic model, which represents the whole sediment column as a single  
box (Hülse et al., 2017). Here, OM deposited on the seafloor is added to the sediment box where  
it gets degraded and dissolved species diffuse through the sediment-water interface in accordance  
with these transformations. This approach thus ignores the vertical extent of the sediments and the  
190 temporary storage of dissolved species (Soetaert et al., 2000). Yet, it is computationally efficient  
and allows differentiating between various fractions of organic matter. Most EMICs incorporate a  
vertically integrated dynamic model for particulate inorganic carbon only (i.e. mainly  $\text{CaCO}_3$ ) and  
just a few consider oxic-only sediment degradation of organic matter (Hülse et al., 2017).

The most complex description of diagenetic organic matter degradation in Earth system models  
195 is the second group of vertically resolved diagenetic models as discussed above (e.g. Heinze et al.,  
1999; Munhoven, 2007; Shaffer et al., 2008). These models solve the one-dimensional reaction-  
transport equation for a number of solid and dissolved species for the upper, bioturbated 10 cm  
of the sediments. Examples of global ESMs employing a vertically resolved diagenetic model are  
NorESM (Tjiputra et al., 2013) and HAMOCC (Palastanga et al., 2011; Ilyina et al., 2013), both  
200 using a version of Heinze et al. (1999). None of the EMICs reviewed by Hülse et al. (2017) use such a  
sediment representation. DCESS (Shaffer et al., 2008) and MBM (Munhoven, 2007) are box models  
employing a vertically resolved diagenetic model. However, in general oxygen is the only TEA  
explicitly modelled and secondary redox reactions and reduced species are completely neglected in  
these approaches. Furthermore, all models represent the bulk OM pool as a single fraction with a  
205 fixed degradation rate constant.

### **Problem with that:**

Obviously, such a simplification of the OM pool can neither account for the observed vast structural complexity in natural organic matter and its resulting different degradation rates nor for the rapid decrease in OM degradability in the uppermost centimetres of the sediments (Arndt et al., 2013). It  
210 has been suggested that at least a 3G approach is necessary to accurately represent organic matter dynamics in this part of the sediments where most OM is degraded (e.g. Soetaert et al., 1996b). Even more restrictive is the use of O<sub>2</sub> as the only TEA and the complete absence of reduced substances and related secondary redox reactions. Even though for the majority of the modern sediments (i.e. in the deep-ocean) O<sub>2</sub> is the primary electron acceptor and Archer et al. (2002) suggested that aerobic  
215 degradation accounts for 66% of total organic matter respiration more recent model and data studies have reported that sulfate reduction is the dominant degradation pathway on a global average (with contributions of 55-76% Canfield et al., 2005; Jørgensen and Kasten, 2006; Thullner et al., 2009). O<sub>2</sub> becomes progressively less important as TEA with decreasing seafloor depth and in shallow waters most of it is used to reoxidise reduced substances produced during anaerobic degradation  
220 (Canfield et al., 2005; Thullner et al., 2009). Thus, the in situ production of e.g. NO<sub>3</sub> and SO<sub>4</sub> through oxidation of NH<sub>4</sub> and H<sub>2</sub>S forms an important sink for O<sub>2</sub> which is entirely neglected in current sediment representations in global models. In addition, due to the lack of an appropriate sedimentary P cycle (with the exception of the HAMOCC version of Palastanga et al. (2011), no current global ESM is able to model the redox dependent P release from marine sediments and its  
225 implications for primary productivity, global biogeochemical cycles and climate.

### **Solution presented here:**

**DH: Include this discussion here:** Analytical approaches with distinct layers were implemented and used in the eighties to describe observed pore water profiles (e.g. Billen, 1982; Goloway and Bender, 1982) and later for inclusion into global Earth system models (Tromp et al., 1995).  
230 However, in addition to the oxic zone these models only describe one anoxic zone, either a denitrification layer (Billen, 1982; Goloway and Bender, 1982) or a sulfate reduction layer (Tromp et al., 1995). In addition, they ignore reoxidation of reduced species produced in the anoxic layers.

In order to provide a more realistic description of organic matter degradation and nutrient cycles in  
235 marine sediments we have developed the OrganicMatter ENabled SEDiment model (OMEN-SED), a new, one-dimensional, numerically efficient reactive transport model. OMEN-SED is the first analytical model to explicitly describe OM cycling as well as associated dynamics of the most important TEAs (i.e. O<sub>2</sub>, NO<sub>3</sub>, SO<sub>4</sub>), related reduced substances (NH<sub>4</sub>, H<sub>2</sub>S), the full suite of secondary-redox reactions, macronutrients (PO<sub>4</sub>) and associated pore water quantities (ALK, DIC). To represent a  
240 redox-dependent sedimentary P cycle we consider the formation and burial of Fe-bound P and authigenic Ca-P minerals. Thus, OMEN-SED captures most of the features of a complex, numerical diagenetic model, however, its computational efficiency allows the coupling to global Earth system

**DH:** which  
Vandenborgh papers? &  
with ERSEM you mean  
the Plymouth model?  
Their model is vertically  
integrated...

models and therefore the investigation of coupled global biogeochemical dynamics over different timescales. Here, the model is presented as a 2G-approach, however, a third, non-degradable OM  
245 fraction can easily be added and OMEN-SED can be further extended to a Multi-G approach.

**SA: started here**

**general notes:**

**-name zones I and II bio and non-bio**

**-name redox zones according to Canfield paper**

250 **- be consistent in the paper and always use the same terminology e.g. zone, boundary,...**

**- don't use I and II for the bioturb, non-bioturb zones and the redox zones. For the redox zones, you actually do not need to use I, II, and III at all, because you name the zone explicitly, so this should be clear**

**DH:** Not 100% sure about redox zones: I don't use suboxic anymore (Canfield and Thamdrup, 2009), and just use anoxic when referring to all zones  $z < z_{\text{ox}}$  together, defined in Sec. 2.2.2)??

## 2 Model Description

255 OMEN-SED a new, one-dimensional, computationally efficient reaction-transport model is designed for the coupling to regional/global biogeochemical and Earth system models. OMEN-SED is implemented as a Fortran version that can be easily coupled to a pelagic model via the coupling routine **OMEN\_SED\_main**. In addition, OMEN-SED exists as a stand-alone version implemented in MATLAB and the entire model can be executed on a standard personal computer in less than 0.1 seconds.

260 The source code of both, the Fortran and the MATLAB stand-alone version, as well as instructions for executing OMEN-SED and for plotting model results are available as a supplement to this paper. The following section provides a detailed description of OMEN-SED. Tables 1 and 15 summarise the biogeochemical reaction network and Tables 9 and 10 provide a glossary of model parameters along with their respective units.

### 2.1 General Model Approach

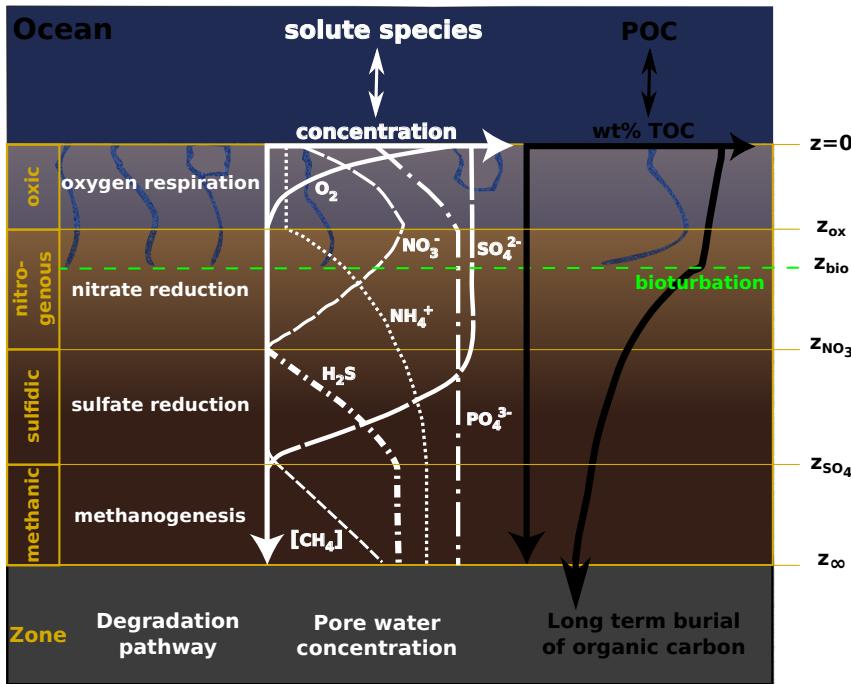

The calculation of benthic uptake, recycling and burial fluxes is based on the vertically resolved conservation equation for solid and dissolved species in porous media (e.g. Berner, 1980; Boudreau, 1997):

$$\frac{\partial \xi C_i}{\partial t} = -\frac{\partial F}{\partial z} + \xi \sum_j R_i^j \quad (1)$$

270 where  $C_i$  is the concentration of biogeochemical species  $i$ ,  $\xi$  equals the porosity  $\phi$  for solute species and  $(1 - \phi)$  for solid species. The term  $z$  is the sediment depth,  $t$  denotes the time,  $F$  summarises the transport fluxes and  $\sum_j R_i^j$  represents the sum of all biogeochemical rates  $j$  affecting species  $i$ .

OMEN-SED accounts for both the advective, as well as the diffusive transport of dissolved and solid species. Solid and dissolved species are buried in the sediment according to a constant burial  
275 rate  $w$ , thus neglecting the effect of sediment compaction (i.e.  $\frac{\partial \phi}{\partial z} = 0$ ) due to mathematical con-

**SA:** maybe include some examples and test figures in supplement?

**Figure 1.** Schematic of the different modelled species and zones in OMEN-SED. Here showing the case  $z_{\text{ox}} < z_{\text{bio}} < z_{\text{NO}_3} < z_{\text{SO}_4}$ .

straints. The molecular diffusion of dissolved species is described by Fick's law applying a species-specific apparent diffusion coefficient,  $D_{\text{mol},i}$ . In addition, the activity of infaunal organisms in the bioturbated zone is simulated using a diffusive term (e.g. Boudreau, 1986), with a constant bioturbation coefficient  $D_{\text{bio}}$  in the bioturbated zone, while  $D_{\text{bio}}$  is set to zero below  $z_{\text{bio}}$ . The pumping activity by burrow-dwelling animals and the resulting ventilation of tubes, the so-called bioirrigation, is encapsulated in a factor  $f_{\text{ir}}$  that enhances the molecular diffusion coefficient (hence,  $D_{i,0} = D_{\text{mol},i} \cdot f_{\text{ir}}$ , Soetaert et al., 1996a). The flux divergence is thus given by:

$$\frac{\partial F}{\partial z} = -\frac{\partial}{\partial z} \left( -\xi D_i \frac{\partial C_i}{\partial z} + \xi w C_i \right) \quad (2)$$

where  $D_i$  is the apparent diffusion coefficient of species  $i$  ( $D_i = D_{i,0} + D_{\text{bio}} = D_{\text{mol},i} \cdot f_{\text{ir}} + D_{\text{bio}}$  for dissolved species and  $D_i = D_{\text{bio}}$  for solid species) and  $w$  is the burial rate.

The reaction network of OMEN-SED accounts for the most important primary and secondary redox reactions, equilibrium reactions, mineral dissolution and precipitation, as well as adsorption and desorption processes that affect the dissolved and solid species explicitly resolved in OMEN-SED. Tables 1 and 15 provide a summary of the reactions and biogeochemical tracers considered in OMEN-SED together with their respective reaction stoichiometry.

Because OMEN-SED is designed for the coupling to Earth system models it requires a computationally efficient solution of Eq. (1) and, thus, solves Eq. (1) analytically, by assuming steady state

**SA:** Tab 1 is maybe a bit redundant? **DH:** I still think it's a good summary/overview!? and the other one could go into the appendix!?

**Table 1.** Reactions and biogeochemical tracers implemented in the reaction network of OMEN-SED. The primary and secondary redox reactions are listed in the sequence they occur with increasing sediment depth.

Description	
Primary redox reactions	Degradation of organic matter via aerobic degradation, denitrification, sulfate reduction, methanogenesis (implicit)
Secondary redox reactions	Oxidation of ammonium and sulfide by oxygen, anaerobic oxidation of methane by sulfate
Adsorption/Desorption	Ad-/Desorption of P on/from Fe(OH) <sub>3</sub> , NH <sub>4</sub> adsorption, PO <sub>4</sub> adsorption
Mineral precipitation	Formation of authigenic P
Biogeochemical tracers	Organic matter (2-G), oxygen, nitrate, ammonium, sulfate, sulfide (hydrogen sulfide), phosphate, Fe-bound P, DIC, ALK

conditions (i.e.  $\frac{\partial C_i}{\partial t} = 0$ ). By describing the reactive term  $R_i^j$  in Eq. (1) more explicitly and applying Eq. (2), the general steady-state transport-reaction equation for a generic tracer  $C_i$  can be formulated

295 as:

$$\frac{\partial C_i}{\partial t} = 0 = D_i \frac{\partial^2 C_i}{\partial z^2} - w \frac{\partial C_i}{\partial z} - k \cdot C_i - \sum_j \alpha_j \exp(-\beta_j z) + Q \quad (3)$$

where  $k$  is a generic reaction rate constant and  $g(z) = -\sum_j \alpha_j \exp(-\beta_j z) + Q$  describes the inhomogeneous reaction (production/consumption) of tracer  $C_i$ , where  $Q$  is a zeroth-order (or constant) 300 rate of  $C_i$  reaction,  $1/\beta_j$  can be interpreted as the length scale and  $\alpha_j$  as the relative importance (or the magnitude at  $z = 0$ ) of reaction  $j$  (Boudreau, 1997).

The analytical solution of Eq. (3) is of the general form:

$$C_i(z) = A \exp(az) + B \exp(bz) + \sum_j \frac{\alpha_j}{D\beta_j^2 - w\beta_j - k} \cdot \exp(-\beta_j z) + \frac{Q}{k} \quad (4)$$

305 where  $A$  and  $B$  are integration constants that are determined with the boundary conditions (see Section 2.3). In addition to assuming steady-state conditions, the sediment column is divided into a number of distinct geochemical zones which do not allow an overlap of degradation pathways (Fig. 1). Each of these zones is characterised by a different set of equations that encapsulate the most pertinent reaction and transport processes within the respective zone in a linear form (see Section 310 2.2), thus allowing a simplification of the coupled set of equations in order to find the analytical solutions (compare e.g. Billen, 1982; Goloway and Bender, 1982; Tromp et al., 1995; Gypens et al., 2008, for similar solutions). More specifically, OMEN-SED divides the sediment column into I) a bioturbated and II) a non-bioturbated zone defined by an imposed, constant bioturbation depth  $z_{\text{bio}}$  (Fig. 1). Furthermore, it resolves the dynamic redox stratification of marine sediments by dividing the 315 sediment into 1) an oxic zone delineated by the oxygen penetration depth  $z_{\text{ox}}$ ; 2) a denitrification (or nitrogenous) zone situated between  $z_{\text{ox}}$  and the nitrate penetration depth  $z_{\text{NO}_3}$ ; 3) a sulfate reduction

**DH:** What about  $\xi$  in Eq. 3? Also include it here? Is this correct?

**DH:** Should it be  $D\beta_i^2 + w\beta_i - k$  in the denom. - see Boudreau (1997) Exp 6-13 Eq. 6.121

**DH:** More Info on these models given in Intro! which Vandenberghe papers? - also ERSEM unclear (see Intro)

zone situated between  $z_{\text{NO}_3}$  and the sulfate penetration depth  $z_{\text{SO}_4}$ ; and 4) a methanogenic zone situated below  $z_{\text{SO}_4}$  (Fig. 1). All penetration depths are dynamically calculated by the model and their depth thus varies in response to changing boundary conditions and forcings. At each dynamic, 320 internal boundary ( $z_b \in \{z_{\text{bio}}, z_{\text{ox}}, z_{\text{NO}_3}, z_{\text{SO}_4}\}$ ) the concentration and flux for the two solutions of the respective reaction-transport equation above and below  $z_b$  is matched (compare e.g. Billen, 1982; Gypens et al., 2008, and Section 2.3.1). The steady-state solution for OM, which follows a simple exponential decay, is calculated first (Section 2.2.1) and drives the oxygen (Section 2.2.2) and other porewater dynamics (Sections 2.2.3 - 2.2.7). The reoxidation of reduced substances is accounted for 325 implicitly by adding a (consumption/production) flux to the internal boundary condition at  $z_{\text{ox}}$  and  $z_{\text{SO}_4}$  for oxygen and the respective tracers (Section 2.2). This simplification has been used previously by Gypens et al. (2008) for nitrate and ammonium and can be justified as it has been shown that the reoxidation mainly occurs at an infinitesimally thin layer at the oxic/anoxic interface (Soetaert et al., 1996b).

330 Based on Eq. (3) and its analytical solution Eq. (4), OMEN-SED calculates the fraction of particulate organic carbon (POC) buried in the sediment,  $f_{\text{POC}}$ , as well as the benthic uptake/return fluxes  $F_{C_i}$  of dissolved species  $C_i$  (in  $\text{mol cm}^{-2} \text{ year}^{-1}$ ) in response to changing boundary conditions and 335 forcings:

$$f_{\text{POC}} = \frac{\text{POC}(z_\infty)}{\text{POC}(0)} \quad (5)$$

$$335 \quad F_{C_i} = \phi(0) \left( D_i \frac{\partial C_i(z)}{\partial z} \Big|_{z=0} - w [C_i(0) - C_i(z_\infty)] \right) \quad (6)$$

where  $w$  is the deposition rate,  $D_i$  is the diffusion coefficient and  $\text{POC}(0)$ ,  $\text{POC}(z_\infty)$ ,  $C_i(0)$ ,  $C_i(z_\infty)$  denotes the concentration of POC and dissolved species  $i$  at the SWI and at the lower sediment boundary, respectively.

## 340 2.2 Conservation Equations and Analytical Solution

### 2.2.1 Organic matter or Particulate Organic Carbon (POC)

In marine sediments, particulate organic carbon (POC) is degraded by heterotrophic activity coupled to the sequential utilisation of terminal electron acceptors according to the free energy gain of the half-reaction ( $\text{O}_2 > \text{NO}_3^- > \text{MnO}_2 > \text{Fe(OH)}_3 > \text{SO}_4^{2-}$ , e.g. Stumm and Morgan, 2012). 345 Here, organic matter degradation is described via a multi G-model approach (Arndt et al., 2013, and references therein), dividing the bulk OM into a number  $i$  of discrete compound classes  $\text{POC}_i$  characterised by class-specific first-order degradation rate constants  $k_i$ . The conservation equation for organic matter dynamics is thus given by:

$$\frac{\partial \text{POC}_i}{\partial t} = 0 = D_{\text{POC}_i} \frac{\partial^2 \text{POC}_i}{\partial z^2} - w \frac{\partial \text{POC}_i}{\partial z} - k_i \cdot \text{POC}_i \quad (7)$$

**DH:** @ Sandra: Not sure what Bernie confused (flux of reduced sp. or general boundary matching) & which paper it is: (Boudreau et al., 1992; Boudreau, 1992)!!??

**Table 2.** OM Boundary conditions applied in OMEN-SED. For the boundaries we define:  $z_{\text{bio}}^- := \lim_{h \rightarrow 0} (z_{\text{bio}} - h)$  and  $z_{\text{bio}}^+ := \lim_{h \rightarrow 0} (z_{\text{bio}} + h)$ . **Awesome! Du bist ja doch ein Mathematiker!**

**DH:** A very poor one though ;)

Boundary	Condition	
$z = 0$	known concentration	1) $\text{POC}_i(0) = \text{POC}_{0i}$
$z = z_{\text{bio}}$	continuity	2) $\text{POC}_i(z_{\text{bio}}^-) = \text{POC}_i(z_{\text{bio}}^+)$ 3) $-D_{\text{bio}} \cdot \frac{\partial \text{POC}_i}{\partial z} \Big _{z_{\text{bio}}^-} = 0$

350 with  $D_{\text{POC}_i} = D_{\text{bio}}$  for  $z \leq z_{\text{bio}}$  and  $D_{\text{POC}_i} = 0$  for  $z > z_{\text{bio}}$ . Integration of equations (7) yields the following general solutions:

I. Bioturbated zone ( $z \leq z_{\text{bio}}$ )

$$355 \quad \begin{aligned} \text{POC}_i^I(z) &= A_{1i} \cdot \exp(a_{1i}z) + B_{1i} \cdot \exp(b_{1i}z) \\ &\stackrel{\text{BC1)}{=} A_{1i} \cdot [\exp(a_{1i}z) - \exp(b_{1i}z)] + \text{POC}_{0i} \cdot \exp(b_{1i}z) \end{aligned} \quad (8)$$

II. Non-bioturbated zone ( $z_{\text{bio}} < z < z_{\text{ox}}$ )

$$\text{POC}_i^{II}(z) = A_{2i} \cdot \exp(a_{2i}z) \quad (9)$$

360 where

$$a_{1i} = \frac{w - \sqrt{w^2 + 4D_{\text{POC}_i} \cdot k_i}}{2D_{\text{POC}_i}}, \quad b_{1i} = \frac{w + \sqrt{w^2 + 4D_{\text{POC}_i} \cdot k_i}}{2D_{\text{POC}_i}}, \quad a_{2i} = -\frac{k_i}{w} \quad (10)$$

Determining the integration constants ( $A_{1,i}$ ,  $B_{1,i}$ ,  $A_{2,i}$ ) requires the definition of a set of boundary conditions (Table 2). For organic matter, OMEN-SED applies a known concentration/flux at the sediment-water interface and assumes continuity across the bottom of the bioturbated zone,  $z_{\text{bio}}$ .

365 See Section 2.3.1 for further details on how to find the analytical solution.

## 2.2.2 Oxygen

OMEN-SED explicitly accounts for oxygen consumption by the aerobic degradation of organic matter within the oxic zone, as well as the oxidation of reduced species (e.g.  $\text{NH}_4$ ,  $\text{H}_2\text{S}$ ,  $\text{CH}_4$ ) produced in the anoxic zones of the sediment (here all zones  $z < z_{\text{ox}}$  combined). In the oxic zone ( $z < z_{\text{ox}}$ ), 370 the aerobic degradation consumes oxygen with a fixed  $\text{O}_2 : \text{C}$  ratio ( $\text{O}_2\text{C}$ , Tab. 10). A predefined fraction,  $\gamma_{\text{NH}_4}$ , of the ammonium produced during the aerobic degradation of OM is nitrified to nitrate, consuming two moles of oxygen per mole of ammonium produced. In addition, OMEN-SED implicitly accounts for the oxygen consumption due to oxidation of reduced species ( $\text{NH}_4$ ,  $\text{H}_2\text{S}$ ) produced below the oxic zone through the flux boundary condition at the dynamically calculated 375 (SA: see section ?? for details) oxygen penetration depth  $z_{\text{ox}}$ . This simplification can be justified as it has been shown that these secondary redox reactions mainly occur at the oxic/anoxic interface

**DH:** comment Sandra, which Section do you mean here?

(Soetaert et al., 1996b). All oxygen consumption processes can thus be formulated as a function of organic matter degradation. The conservation equation for oxygen is given by: **SA: I'd show the POC substitution in the equations below:**

380

$$\frac{\partial O_2}{\partial t} = 0 = D_{O_2} \frac{\partial^2 O_2}{\partial z^2} - w \frac{\partial O_2}{\partial z} - \frac{1-\phi}{\phi} \sum_i k_i \cdot [O_2 C + 2\gamma_{NH_4} NC_i] \cdot POC_i(z) \quad (11)$$

I Bioturbated zone ( $z \leq z_{bio}$ )

385

$$\frac{\partial O_2^I}{\partial t} \stackrel{g}{=} D_{O_2}^I \frac{\partial^2 O_2}{\partial z^2} - w \frac{\partial O_2}{\partial z} - \frac{1-\phi}{\phi} \sum_i k_i \cdot [O_2 C + 2\gamma_{NH_4} NC_i] \cdot \left( A_{1i} \cdot [exp(a_{1i}z) - exp(b_{1i}z)] + POC_{0i} \cdot exp(b_{1i}z) \right)$$

II Non-bioturbated zone ( $z_{bio} < z < z_{ox}$ )

$$\frac{\partial O_2^{II}}{\partial t} \stackrel{g}{=} D_{O_2}^{II} \frac{\partial^2 O_2}{\partial z^2} - w \frac{\partial O_2}{\partial z} - \frac{1-\phi}{\phi} \sum_i k_i \cdot [O_2 C + 2\gamma_{NH_4} NC_i] \cdot \left( A_{2i} \cdot exp(a_{2i}z) \right)$$

390 where  $D_{O_2}^I$  and  $D_{O_2}^{II}$  denote the  $O_2$  diffusion coefficient for the bioturbated and non-bioturbated zone, respectively. The term  $\frac{1-\phi}{\phi}$  accounts for the volume conversion from solid to dissolved phase and  $NC_i$  is the nitrogen to carbon ratio in OM. **SA: explain all terms**

Integration yields the following analytical solution for each zone:

I Bioturbated zone ( $z \leq z_{bio}$ ):

$$O_2^I(z) = A_{O_2}^1 + B_{O_2}^1 \cdot exp(b_{O_2}^1 z) + \sum_i \Phi_{1,i}^I \cdot exp(a_{1i}z) + \sum_i \Phi_{1,i}^{II} \cdot exp(b_{1i}z) + \sum_i \Phi_{1,i}^{III} \cdot exp(b_{1i}z) \quad (12)$$

395

II Non-bioturbated zone ( $z_{bio} < z < z_{ox}$ )

$$O_2^{II}(z) = A_{O_2}^2 + B_{O_2}^2 \cdot exp(b_{O_2}^2 z) + \sum_i \Phi_{i,2}^I \cdot exp(a_{2i}z) \quad (13)$$

400 with

$$\begin{aligned} b_{O_2}^1 &= \frac{w}{D_{O_2}^I}, \quad b_{O_2}^2 = \frac{w}{D_{O_2}^{II}} \\ \Phi_{1,i}^I &= \frac{1-\phi}{\phi} \cdot \frac{k_i \cdot (O_2 C + 2\gamma_{NH_4} NC_i) \cdot A_{1i}}{D_{O_2}^I (-a_{1i})^2 - w \cdot (-a_{1i})}, \quad \Phi_{1,i}^{II} = -\frac{1-\phi}{\phi} \cdot \frac{k_i \cdot (O_2 C + 2\gamma_{NH_4} NC_i) \cdot A_{1i}}{D_{O_2}^I (-b_{1i})^2 - w \cdot (-b_{1i})} \\ \Phi_{1,i}^{III} &= \frac{1-\phi}{\phi} \cdot \frac{k_i \cdot (O_2 C + 2\gamma_{NH_4} NC_i) \cdot POC_{0i}}{D_{O_2}^I (-b_{1i})^2 - w \cdot (-b_{1i})} \\ \Phi_{i,2}^I &:= \frac{1-\phi}{\phi} \cdot \frac{k_i \cdot (O_2 C + 2\gamma_{NH_4} NC_i) \cdot A_{2i}}{D_{O_2}^{II} (-a_{2i})^2 - w \cdot (-a_{2i})} \end{aligned}$$

405

Determining the four integration constants ( $A_{O_2}^1, B_{O_2}^1, A_{O_2}^2, B_{O_2}^2$ , see Section 2.3 for details), as well as the *a priori* unknown oxygen penetration depth requires the definition of five boundary

**DH:** you mean the way I did it or in the solution?  
I think it's easier to understand (also how to get the solution) if it's done in the ODE

**DH:** Other terms are explained earlier in 2.2.2 or 2.2.1

**Table 3.** Boundary conditions for oxygen. For the boundaries we define:  $z_{\text{bio}}^- := \lim_{h \rightarrow 0} (z_{\text{bio}} - h)$  and  $z_{\text{bio}}^+ := \lim_{h \rightarrow 0} (z_{\text{bio}} + h)$ .

Boundary	Condition	
$z = 0$	known concentration	1) $O_2(0) = O_{20}$
$z = z_{\text{bio}}$	continuity	2) $O_2(z_{\text{bio}}^-) = O_2(z_{\text{bio}}^+)$
$z = z_{\text{ox}}$	$O_2$ consumption ( $z_{\text{ox}} = z_\infty$ )	3) $-(D_{O_2,0} + D_{\text{bio}}) \cdot \frac{\partial O_2}{\partial z} \Big _{z_{\text{bio}}^-} = -D_{O_2,0} \cdot \frac{\partial O_2}{\partial z} \Big _{z_{\text{bio}}^+}$ 4) <b>IF</b> ( $O_2(z_\infty) > 0$ ) 4.1) $\frac{\partial O_2}{\partial z} \Big _{z_{\text{ox}}} = 0$ <b>ELSE</b>
	$(z_{\text{ox}} < z_\infty)$	4.2) $O_2(z_{\text{ox}}) = 0 \quad \text{and} \quad -D_{O_2} \cdot \frac{\partial O_2}{\partial z} \Big _{z_{\text{ox}}} = F_{\text{red}}(z_{\text{ox}})$ $F_{\text{red}}(z_{\text{ox}}) = \frac{1-\phi}{\phi} \cdot \int_{z_{\text{ox}}}^\infty \sum_i (2\gamma_{\text{NH}_4} \text{NC}_i + 2\gamma_{\text{H}_2\text{S}} \text{SO}_4 \text{C}) k_i \text{POC}_i dz$
	with flux from below	

conditions (see Table 3). At the sediment-water interface, OMEN-SED applies a Dirichlet condition (i.e. known concentration) and assumes concentration and flux continuity across the bottom of the bioturbated zone,  $z_{\text{bio}}$ . The oxygen penetration depth  $z_{\text{ox}}$  marks the lower boundary and is dynamically calculated as the depth at which  $O_2(z) = 0$ . Therefore, OMEN-SED applies a Dirichlet boundary condition  $O_2(z_{\text{ox}}) = 0$ . In addition, a flux boundary is applied that implicitly accounts for the oxygen consumption by the partial oxidation of  $\text{NH}_4$  and  $\text{H}_2\text{S}$  diffusing into the oxic zone from below (BC 4.2, Table 3). It is assumed that respective fractions ( $\gamma_{\text{NH}_4}$  and  $\gamma_{\text{H}_2\text{S}}$ ) are directly reoxidised at the oxic/anoxic interface. OMEN-SED iteratively solves for  $z_{\text{ox}}$  by first testing if there is oxygen left at  $z_\infty$  (i.e.  $O_2(z_\infty) > 0$ ) and, otherwise, by finding the root for the flux boundary condition 4.2 (Table 3). If  $z_{\text{ox}} = z_\infty$ , a zero flux boundary condition is applied as lower boundary condition.

### 2.2.3 Nitrate and Ammonium

Nitrogen dynamics in OMEN-SED are controlled by the metabolic production of ammonium, nitrification, denitrification as well as ammonium adsorption. Ammonium is produced by organic matter degradation in both the oxic and anoxic zones, while denitrification consumes nitrate in the denitrification zone with a fixed  $\text{NO}_3 : \text{C}$  ratio ( $\text{NO}_3\text{C}$ , Tab. 10) **SA: need explanation**. The adsorption of ammonium to sediment particles is formulated as an equilibrium process with constant equilibrium adsorption coefficient  $K_{\text{NH}_4}$ , thus assuming that the adsorption is fast compared with the characteristic time scales of transport processes (Wang and Van Cappellen, 1996). In addition, a defined fraction,  $\gamma_{\text{NH}_4}$ , of metabolically produced ammonium is directly nitrified to nitrate in the oxic zone, while the nitrification of upward diffusing ammonium produced in the sulfidic and methanic zones is implicitly accounted for in the boundary conditions. The conservation equations for ammonium and nitrate are thus given by:

**DH:** Edited explanation of finding  $z_{\text{ox}}$

**DH:** explanation sufficient?

1. Oxic zone ( $z \leq z_{\text{ox}}$ )

$$\frac{\partial \text{NO}_3^I}{\partial t} = 0 = D_{\text{NO}_3} \frac{\partial^2 \text{NO}_3^I}{\partial z^2} - w \frac{\partial \text{NO}_3^I}{\partial z} + \gamma_{\text{NH}_4} \frac{1-\phi}{\phi} \cdot \sum_i \text{NC}_i \cdot k_i \cdot \text{POC}_i(z) \quad (14)$$

$$\frac{\partial \text{NH}_4^I}{\partial t} = 0 = \frac{D_{\text{NH}_4}}{1+K_{\text{NH}_4}} \frac{\partial^2 \text{NH}_4^I}{\partial z^2} - w \frac{\partial \text{NH}_4^I}{\partial z} + \frac{1-\gamma_{\text{NH}_4}}{1+K_{\text{NH}_4}} \cdot \frac{1-\phi}{\phi} \cdot \sum_i \text{NC}_i \cdot k_i \cdot \text{POC}_i(z) \quad (15)$$

435

2. Denitrification (or nitrogenous) zone ( $z_{\text{ox}} < z \leq z_{\text{NO}_3}$ )

$$\frac{\partial \text{NO}_3^{II}}{\partial t} = 0 = D_{\text{NO}_3} \frac{\partial^2 \text{NO}_3^{II}}{\partial z^2} - w \frac{\partial \text{NO}_3^{II}}{\partial z} - \frac{1-\phi}{\phi} \text{NO}_3 \text{C} \cdot \sum_i k_i \cdot \text{POC}_i(z) \quad (16)$$

440

$$\frac{\partial \text{NH}_4^{II}}{\partial t} = 0 = \frac{D_{\text{NH}_4}}{1+K_{\text{NH}_4}} \frac{\partial^2 \text{NH}_4^{II}}{\partial z^2} - w \frac{\partial \text{NH}_4^{II}}{\partial z} \quad (17)$$

3. Sulfidic and methanic zone ( $z_{\text{NO}_3} < z \leq z_{\infty}$ )

$$\frac{\partial \text{NH}_4^{III}}{\partial t} = 0 = \frac{D_{\text{NH}_4}}{1+K_{\text{NH}_4}} \frac{\partial^2 \text{NH}_4^{III}}{\partial z^2} - w \frac{\partial \text{NH}_4^{III}}{\partial z} + \frac{1}{1+K_{\text{NH}_4}} \cdot \frac{1-\phi}{\phi} \cdot \sum_i \text{NC}_i \cdot k_i \cdot \text{POC}_i(z) \quad (18)$$

where  $D_{\text{NO}_3}$  and  $D_{\text{NH}_4}$  denote the diffusion coefficients for  $\text{NO}_3$  and  $\text{NH}_4$  which depend on the bioturbation status of the respective geochemical zone (compare Section 2.3.1). Integration of Eq. (14) - (18) yields the analytical solutions, which are not further developed here but follow the procedure outlined in Section 2.2.2 for oxygen (also see Section 2.3.1 for more details on how to find the analytical solution). Table 4 summarises the boundary conditions applied in OMEN-SED to solve Eq. (14) - (18) and to find the *a priori* unknown nitrate penetration depth,  $z_{\text{NO}_3}$ . The model assumes known bottom water concentrations for both species, the complete consumption of nitrate at the nitrate penetration depth (in case  $z_{\text{NO}_3} < z_{\infty}$ ) and no change in nitrate and ammonium flux at  $z_{\infty}$ . In addition, concentration and diffusive flux continuity across  $z_{\text{bio}}$  and  $z_{\text{ox}}$  is considered for  $\text{NO}_3$  and  $\text{NH}_4$ . Furthermore, the reoxidation of upward-diffusing reduced ammonium is accounted for in the oxic-anoxic boundary condition for nitrate and ammonium. OMEN-SED iteratively solves for  $z_{\text{NO}_3}$  by first testing if there is nitrate left at  $z_{\infty}$  (i.e.  $\text{NO}_3(z_{\infty}) > 0$ ) and, otherwise, by finding the root for the flux boundary condition 6.2 (Table 4).

**DH:** all other params explained earlier

## 2.2.4 Sulfate and Sulfide

Below the denitrification zone ( $z > z_{\text{NO}_3}$ ), organic matter degradation is coupled to sulfate reduction, consuming sulfate and producing hydrogen sulfide with a fixed  $\text{SO}_4 : \text{C}$  ratio ( $\text{SO}_4 \text{C}$ , Tab. 10). In addition, the anaerobic oxidation of upward diffusing methane (AOM) produced below the sulfate penetration and the associated consumption of sulfate and production of sulfide; as well as the production of sulfate and consumption of sulfide through sulfide oxidation are implicitly accounted

**Table 4.** Boundary conditions for nitrate and ammonium. For the boundaries we define:  $z_-^- := \lim_{h \rightarrow 0} (z_- - h)$  and  $z_-^+ := \lim_{h \rightarrow 0} (z_- + h)$ .

Boundary	Condition	
$z = 0$	known concentration	1) $\text{NO}_3(0) = \text{NO}_{30}$
$z = z_{\text{bio}}$	continuity	2) $\text{NO}_3(z_{\text{bio}}^-) = \text{NO}_3(z_{\text{bio}}^+)$
$z = z_{\text{ox}}$	continuity	3) $-(D_{\text{NO}_3,0} + D_{\text{bio}}) \cdot \frac{\partial \text{NO}_3}{\partial z}  _{z_{\text{bio}}^-} = -D_{\text{NO}_3,0} \cdot \frac{\partial \text{NO}_3}{\partial z}  _{z_{\text{bio}}^+}$
	where:	4) $\text{NO}_3(z_{\text{ox}}^-) = \text{NO}_3(z_{\text{ox}}^+)$
$z = z_{\text{NO}_3}$	$\text{NO}_3$ consumption ( $z_{\text{NO}_3} = z_\infty$ )	5) $-D_{\text{NO}_3} \cdot \frac{\partial \text{NO}_3}{\partial z}  _{z_{\text{ox}}^-} + \gamma_{\text{NH}_4} \cdot F_{\text{NH}_4}(z_{\text{ox}}) = -D_{\text{NO}_3} \cdot \frac{\partial \text{NO}_3}{\partial z}  _{z_{\text{ox}}^+}$ $F_{\text{NH}_4}(z_{\text{ox}}) = \frac{1}{1+K_{\text{NH}_4}} \cdot \frac{1-\phi}{\phi} \cdot \int_{z_{\text{NO}_3}}^\infty \sum_i k_i \cdot \text{NC}_i \cdot \text{POC}_i dz$
		6) <b>IF</b> ( $\text{NO}_3(z_\infty) > 0$ )
		6.1) $\frac{\partial \text{NO}_3}{\partial z}  _{z_{\text{NO}_3}} = 0$
		<b>ELSE</b>
		6.2) $\text{NO}_3(z_{\text{NO}_3}) = 0 \quad \text{and} \quad \frac{\partial \text{NO}_3}{\partial z}  _{z_{\text{NO}_3}} = 0$
$z = 0$	known concentration	1) $\text{NH}_4(0) = \text{NH}_{40}$
$z = z_{\text{bio}}$	continuity	2) $\text{NH}_4(z_{\text{bio}}^-) = \text{NH}_4(z_{\text{bio}}^+)$
$z = z_{\text{ox}}$	continuity	3) $-\frac{D_{\text{NH}_4,0} + D_{\text{bio}}}{1+K_{\text{NH}_4}} \cdot \frac{\partial \text{NH}_4}{\partial z}  _{z_{\text{bio}}^-} = -\frac{D_{\text{NH}_4,0}}{1+K_{\text{NH}_4}} \cdot \frac{\partial \text{NH}_4}{\partial z}  _{z_{\text{bio}}^+}$
	where:	4) $\text{NH}_4(z_{\text{ox}}^-) = \text{NH}_4(z_{\text{ox}}^+)$
$z = z_{\text{NO}_3}$	continuity flux	5) $-\frac{D_{\text{NH}_4}}{1+K_{\text{NH}_4}} \cdot \frac{\partial \text{NH}_4}{\partial z}  _{z_{\text{ox}}^-} - \gamma_{\text{NH}_4} \cdot F_{\text{NH}_4}(z_{\text{ox}}) = -\frac{D_{\text{NH}_4}}{1+K_{\text{NH}_4}} \cdot \frac{\partial \text{NH}_4}{\partial z}  _{z_{\text{ox}}^+}$ $F_{\text{NH}_4}(z_{\text{ox}}) = \frac{1}{1+K_{\text{NH}_4}} \cdot \frac{1-\phi}{\phi} \cdot \int_{z_{\text{NO}_3}}^\infty \sum_i k_i \cdot \text{NC}_i \cdot \text{POC}_i dz$
$z = z_\infty$	zero $\text{NH}_4$ flux	6) $\text{NH}_4(z_{\text{NO}_3}^-) = \text{NH}_4(z_{\text{NO}_3}^+)$
		7) $-\frac{D_{\text{NH}_4}}{1+K_{\text{NH}_4}} \cdot \frac{\partial \text{NH}_4}{\partial z}  _{z_{\text{NO}_3}^-} = -\frac{D_{\text{NH}_4}}{1+K_{\text{NH}_4}} \cdot \frac{\partial \text{NH}_4}{\partial z}  _{z_{\text{NO}_3}^+}$
		8) $\frac{\partial \text{NH}_4}{\partial z}  _{z_\infty} = 0$

for through the boundary conditions (Table 5). The conservation equations for sulfate and sulfide are thus given by:

465

### 1. Oxic and nitrogenous zone ( $z \leq z_{\text{NO}_3}$ )

$$\frac{\partial \text{SO}_4^{I}}{\partial t} = 0 = D_{\text{SO}_4} \frac{\partial^2 \text{SO}_4^{I}}{\partial z^2} - w \frac{\partial \text{SO}_4^{I}}{\partial z} \quad (19)$$

$$470 \quad \frac{\partial \text{H}_2\text{S}^I}{\partial t} = 0 = D_{\text{H}_2\text{S}} \frac{\partial^2 \text{H}_2\text{S}^I}{\partial z^2} - w \frac{\partial \text{H}_2\text{S}^I}{\partial z} \quad (20)$$

### 2. Sulfidic zone ( $z_{\text{NO}_3} < z \leq z_{\text{SO}_4}$ )

$$\frac{\partial \text{SO}_4^{II}}{\partial t} = 0 = D_{\text{SO}_4} \frac{\partial^2 \text{SO}_4^{II}}{\partial z^2} - w \frac{\partial \text{SO}_4^{II}}{\partial z} - \frac{1-\phi}{\phi} \cdot \sum_i \text{SO}_4 \text{C} \cdot k_i \cdot \text{POC}_i(z) \quad (21)$$

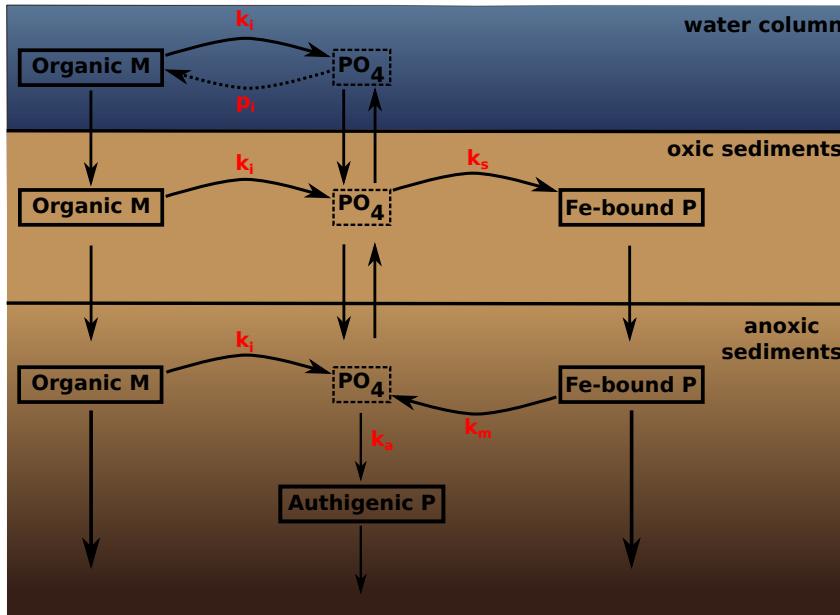

$$\frac{\partial \text{H}_2\text{S}^{II}}{\partial t} = 0 = D_{\text{H}_2\text{S}} \frac{\partial^2 \text{H}_2\text{S}^{II}}{\partial z^2} - w \frac{\partial \text{H}_2\text{S}^{II}}{\partial z} + \frac{1-\phi}{\phi} \cdot \sum_i \text{SO}_4 \text{C} \cdot k_i \cdot \text{POC}_i(z) \quad (22)$$

475 3. Methanic zone ( $z_{SO_4} < z \leq z_\infty$ )

$$\frac{\partial H_2S^{III}}{\partial t} = 0 = D_{H_2S} \frac{\partial^2 H_2S^{III}}{\partial z^2} - w \frac{\partial H_2S^{III}}{\partial z} \quad (23)$$

where  $D_{SO_4}$  and  $D_{H_2S}$  denote the diffusion coefficients for  $SO_4$  and  $H_2S$  which depend on the bioturbation status of the respective geochemical zone (compare Section 2.3.1). Integration of Eq. 480 (19) - (23) yields the analytical solution and Table 5 summarises the boundary conditions applied. OMEN-SED assumes known concentrations at the sediment-water interface and continuity across the bioturbation depth and the nitrate penetration depth. The reoxidation of reduced  $H_2S$  to  $SO_4$  is accounted for implicitly via the oxic-anoxic boundary condition for both species, while reduction of  $SO_4$  and the associated production of  $H_2S$  via AOM is accounted for through the respective 485 boundary conditions at  $z_{SO_4}$ . In case  $z_{SO_4} < z_\infty$ , OMEN-SED assumes zero sulfate concentration at  $z_{SO_4}$  and its diffusive flux must equal the amount of methane produced below; or, in case  $z_{SO_4} = z_\infty$ , a zero flux condition for sulfate is considered. OMEN-SED iteratively solves for  $z_{SO_4}$  by first testing if there is sulfate left at  $z_\infty$  (i.e.  $SO_4(z_\infty) > 0$ ) and, otherwise, by finding the root for the flux boundary condition 8.2 (Table 5). At the lower boundary  $z_\infty$  zero flux of  $H_2S$  is considered.

490 **2.2.5 Phosphate**

**Figure 2.** A schematic of the sedimentary P cycle in OMEN-SED. Red numbers represent kinetic rate constants for phosphorus dynamics (compare Table 10;  $p_i$  represents uptake rate of  $PO_4$  via primary production in shallow environments). Adapted from Slomp et al. (1996).

**Table 5.** Boundary conditions for sulfate and sulfide. For the boundaries we define:  $z_-^- := \lim_{h \rightarrow 0} (z_- - h)$  and  $z_-^+ := \lim_{h \rightarrow 0} (z_- + h)$ .

Boundary	Condition	
$z = 0$	known concentration	1) $\text{SO}_4(0) = \text{SO}_{40}$

$z = z_\infty$	zero H <sub>2</sub> S flux	10) $\frac{\partial \text{H}_2\text{S}}{\partial z}  _{z_\infty} = 0$

The biogeochemical description of phosphorus (P) dynamics builds on the work of Slomp et al. (1996) and accounts for phosphorus recycling through organic matter degradation, adsorption onto sediments and iron(III) hydroxides (Fe-bound P), as well as carbonate fluorapatite (CFA or authigenic P) formation (see Figure 2 for a schematic overview of the sedimentary P cycle). In the oxic zone of the sediment,  $\text{PO}_4$  liberated through organic matter degradation can adsorb to iron(III) hydroxides forming Fe-bound P (or M, Slomp et al., 1998). Below the oxic zone,  $\text{PO}_4$  is not only produced via organic matter degradation but can also be released from the Fe-bound P pool due to the reduction of iron(III) hydroxides under anoxic conditions. Furthermore, in these zones phosphate concentrations build up and pore waters can thus become supersaturated with respect to carbonate fluorapatite, thus triggering the authigenic formation of CFA (Van Cappellen and Berner, 1988). Phosphorus bound in these authigenic minerals represents a permanent sink for reactive phosphorus (Slomp et al., 1996). As for ammonium, the adsorption of P to the sediment matrix is treated as an equilibrium processes, parameterised with dimensionless adsorption coefficients for the oxic and anoxic zone, respectively ( $K_{\text{PO}_4}^{\text{ox}}$ ,  $K_{\text{PO}_4}^{\text{anox}}$  Slomp et al., 1998). The sorption and desorption of P to iron(III) hydroxides as well as the authigenic fluorapatite formation are described as first-order reactions with rate constants  $k_s$ ,  $k_m$  and  $k_a$ , respectively (Table 10). The rate of the respective process is calculated as the product of the rate constant and the difference between the current concentration (of  $\text{PO}_4$  and M) and an equilibrium or asymptotic concentration Slomp et al. (1996). The asymptotic Fe-bound P concentration is  $M^\infty$  and the equilibrium concentration for P sorption and authigenic fluorapatite formation are  $\text{PO}_4^s$  and  $\text{PO}_4^a$ , respectively (Table 10).

**DH:** enough Info on  
Fe-adsorption and M?

### 1. Oxic zone ( $z \leq z_{\text{ox}}$ )

$$\frac{\partial \text{PO}_4^I}{\partial t} = \frac{D_{\text{PO}_4}}{1 + K_{\text{PO}_4}^{\text{ox}}} \frac{\partial^2 \text{PO}_4^I}{\partial z^2} - w \frac{\partial \text{PO}_4^I}{\partial z} + \frac{1-\phi}{\phi} \frac{1}{1 + K_{\text{PO}_4}^{\text{ox}}} \sum_i (\text{PC}_i \cdot k_i \cdot \text{POC}_i(z)) - \frac{k_s}{1 + K_{\text{PO}_4}^{\text{ox}}} (\text{PO}_4^I - \text{PO}_4^s) \quad (24)$$

$$\frac{\partial M^I}{\partial t} = D_M \frac{\partial^2 M^I}{\partial z^2} - w \frac{\partial M^I}{\partial z} + \frac{\phi}{1-\phi} k_s (\text{PO}_4^I - \text{PO}_4^s) \quad (25)$$

### 2. Anoxic zones ( $z_{\text{ox}} < z \leq z_\infty$ )

$$\frac{\partial M^{II}}{\partial t} = D_M \frac{\partial^2 M^{II}}{\partial z^2} - w \frac{\partial M^{II}}{\partial z} - k_m (M^{II} - M^\infty) \quad (26)$$

$$\frac{\partial \text{PO}_4^{II}}{\partial t} = \frac{D_{\text{PO}_4}}{1 + K_{\text{PO}_4}^{\text{anox}}} \frac{\partial^2 \text{PO}_4^{II}}{\partial z^2} - w \frac{\partial \text{PO}_4^{II}}{\partial z} + \frac{1-\phi}{\phi} \frac{1}{1 + K_{\text{PO}_4}^{\text{anox}}} \sum_i (\text{PC}_i \cdot k_i \cdot \text{POC}_i(z)) - \frac{k_a}{1 + K_{\text{PO}_4}^{\text{anox}}} (\text{PO}_4^{II} - \text{PO}_4^a) + \frac{(1-\phi)}{\phi} \frac{k_m}{1 + K_{\text{PO}_4}^{\text{anox}}} (M^{II} - M^\infty) \quad (27)$$

where  $D_{\text{PO}_4}$  denotes the diffusion coefficient for  $\text{PO}_4$  which depends on the bioturbation status of the respective geochemical zone and  $D_M = D_{\text{bio}}$  for  $z \leq z_{\text{bio}}$  and  $D_M = 0$  for  $z > z_{\text{bio}}$  (compare Section 2.3.1). Integration of Eq. (24) - (27) yields the analytical solution and Table 6 summarises

**Table 6.** Boundary conditions for phosphate and Fe-bound P (M). For the boundaries we define:  $z_-^- := \lim_{h \rightarrow 0} (z_- - h)$  and  $z_+^+ := \lim_{h \rightarrow 0} (z_- + h)$ .

Boundary	Condition	
$z = 0$	known concentration	1) $\text{PO}_4(0) = \text{PO}_{40}$
$z = z_{\text{bio}}$	continuity	2) $\text{PO}_4(z_{\text{bio}}^-) = \text{PO}_4(z_{\text{bio}}^+)$
	flux	3) $(D_{\text{PO}_4,0} + D_{\text{bio}}) \cdot \frac{\partial \text{PO}_4}{\partial z}  _{z_{\text{bio}}^-} = D_{\text{PO}_4,0} \cdot \frac{\partial \text{PO}_4}{\partial z}  _{z_{\text{bio}}^+}$
$z = z_{\text{ox}}$	continuity	4) $\text{PO}_4(z_{\text{ox}}^-) = \text{PO}_4(z_{\text{ox}}^+)$
	flux	5) $-\frac{D_{\text{PO}_4}}{1 + K_{\text{PO}_4}^{2z}} \cdot \frac{\partial \text{PO}_4}{\partial z}  _{z_{\text{ox}}^-} = -\frac{D_{\text{PO}_4}}{1 + K_{\text{PO}_4}^{\text{anox}}} \cdot \frac{\partial \text{PO}_4}{\partial z}  _{z_{\text{ox}}^+}$
$z = z_\infty$	flux	10) $\frac{\partial \text{PO}_4}{\partial z}  _{z_\infty} = 0$
$z = 0$	known concentration	1) $M(0) = M_0$
$z = z_{\text{bio}}$	continuity	2) $M(z_{\text{bio}}^-) = M(z_{\text{bio}}^+)$
	flux	3) $\frac{\partial M}{\partial z}  _{z_{\text{bio}}^-} = \frac{\partial M}{\partial z}  _{z_{\text{bio}}^+}$
$z = z_{\text{ox}}$	continuity	4) $M(z_{\text{ox}}^-) = M(z_{\text{ox}}^+)$
	flux	5) $\frac{\partial M}{\partial z}  _{z_{\text{ox}}^-} = \frac{\partial M}{\partial z}  _{z_{\text{ox}}^+}$
$z = z_\infty$	asymptotic concentration	10) $M(z_\infty) = M_\infty$

525 the boundary conditions applied in OMEN-SED. The model assumes known bottom water concentrations and equal concentrations and diffusive fluxes at  $z_{\text{bio}}$  and  $z_{\text{ox}}$  for both species. A no flux boundary condition is applied at  $z_\infty$ .

## 2.2.6 Dissolved Inorganic Carbon (DIC)

OMEN-SED accounts for the production of dissolved inorganic carbon (DIC) through organic 530 matter degradation, as well as methane oxidation. Organic matter degradation produces dissolved inorganic carbon with a stoichiometric DIC : C ratio of 1:2 in the methanic zone and 1:1 in the rest of the sediment column ( $\text{DICC}^{\text{II}}$  and  $\text{DICC}^{\text{I}}$  respectively). DIC production through methane oxidation is implicitly taken into account through the boundary condition at  $z_{\text{SO}_4}$ . The conservation 535 equations for DIC are thus given by:

**DH:** I think what I wrote before also applies: a asymptotic Fe-bound P concentration at  $z_\infty$  is assumed! (but is the same as “no flux condition” as it is now?)

**SA:** need to say something about carbonates here

1. Oxic, nitrogenous and sulfidic zone ( $z \leq z_{\text{SO}_4}$ )

$$\frac{\partial \text{DIC}^{\text{I}}}{\partial t} = 0 = D_{\text{DIC}} \frac{\partial^2 \text{DIC}^{\text{I}}}{\partial z^2} - w \frac{\partial \text{DIC}^{\text{I}}}{\partial z} + \frac{1 - \phi}{\phi} \cdot \sum_i \text{DICC}^{\text{I}} \cdot k_i \cdot \text{POC}_i(z) \quad (28)$$

2. Methanic zone ( $z_{\text{SO}_4} < z \leq z_\infty$ )

$$\frac{\partial \text{DIC}^{\text{II}}}{\partial t} = 0 = D_{\text{DIC}} \frac{\partial^2 \text{DIC}^{\text{II}}}{\partial z^2} - w \frac{\partial \text{DIC}^{\text{II}}}{\partial z} + \frac{1 - \phi}{\phi} \cdot \sum_i \text{DICC}^{\text{II}} \cdot k_i \cdot \text{POC}_i(z) \quad (29)$$

where  $D_{\text{DIC}}$  denotes the diffusion coefficient for DIC which depends on the bioturbation status of the respective geochemical zone. Integration of Eq. (28) and (29) yields the analytical solution and

**Table 7.** Boundary conditions for DIC. For the boundaries we define:  $z_-^- := \lim_{h \rightarrow 0} (z_- - h)$  and  $z_-^+ := \lim_{h \rightarrow 0} (z_- + h)$ .

Boundary	Condition	
$z = 0$	known concentration	1) $\text{DIC}(0) = \text{DIC}_0$
$z = z_{\text{bio}}$	continuity	2) $\text{DIC}(z_{\text{bio}}^-) = \text{DIC}(z_{\text{bio}}^+)$
	flux	3) $-(D_{\text{DIC},0} + D_{\text{bio}}) \cdot \frac{\partial \text{DIC}}{\partial z} \Big _{z_{\text{bio}}^-} = -D_{\text{DIC},0} \cdot \frac{\partial \text{DIC}}{\partial z} \Big _{z_{\text{bio}}^+}$
$z = z_{\text{SO}_4}$	continuity	4) $\text{DIC}(z_{\text{SO}_4}^-) = \text{DIC}(z_{\text{SO}_4}^+)$
	flux (with AOM)	5) $-D_{\text{DIC}} \cdot \frac{\partial \text{DIC}}{\partial z} \Big _{z_{\text{SO}_4}^-} + \gamma_{\text{CH}_4} \cdot F_{\text{CH}_4}(z_{\text{SO}_4}) = -D_{\text{DIC}} \cdot \frac{\partial \text{DIC}}{\partial z} \Big _{z_{\text{SO}_4}^+}$
	where:	$F_{\text{CH}_4}(z_{\text{SO}_4}) = \frac{1-\phi}{\phi} \cdot \int_{z_{\text{SO}_4}}^{\infty} \sum_i \text{MC} \cdot k_i \cdot \text{POC}_i dz$
$z = z_\infty$	zero DIC flux	6) $\frac{\partial \text{DIC}}{\partial z} \Big _{z_\infty} = 0$

Table 7 summarises the boundary conditions applied in OMEN-SED. A Dirichlet condition is applied at the sediment-water interface. In addition, the model assumes a zero flux through the lower boundary  $z_\infty$  and continuity across the bottom of the bioturbated zone, as well as the sulfate penetration depth. An additional flux boundary condition at  $z_{\text{SO}_4}$ , implicitly accounts for DIC production through anaerobic oxidation of methane (Table 7 Eq. 5).

## 2.2.7 Alkalinity

Organic matter degradation and secondary redox reactions exert a complex influence on alkalinity (Wolf-Gladrow et al., 2007). To model alkalinity, OMEN-SED divides the sediment column into four geochemical zones, where different equations describe the biogeochemical processes using variable stoichiometric coefficients (compare Tables 10). Above  $z_{\text{ox}}$ , the combined effects of  $\text{NH}_4$  and P release due to aerobic OM degradation increases alkalinity according to  $\text{ALK}^{\text{OX}}$  whereas nitrification decreases alkalinity with stoichiometry  $\text{ALK}^{\text{NIT}}$ . In the remaining three zones anaerobic OM degradation generally results in an increase in alkalinity, with the exact magnitude depending on the nature of the terminal electron acceptor used (i.e.  $\text{ALK}^{\text{DEN}}$ ,  $\text{ALK}^{\text{SUL}}$ ,  $\text{ALK}^{\text{MET}}$ ). In addition, the effect of secondary redox reactions, such as nitrification, methane and sulfide oxidation are implicitly accounted for in the boundary conditions.

**SA: TODO: again need to mention carboantes**

In OMEN-SED, the conservation equations for alkalinity is thus given by:

### 1. Oxic zone ( $z \leq z_{\text{ox}}$ )

$$\frac{\partial \text{ALK}^I}{\partial t} = 0 = D_{\text{ALK}} \frac{\partial^2 \text{ALK}^I}{\partial z^2} - w \frac{\partial \text{ALK}^I}{\partial z} + \frac{1-\phi}{\phi} \cdot \sum_i \left( \text{ALK}^{\text{NIT}} \cdot \frac{\gamma_{\text{NH}_4}}{1+K_{\text{NH}_4}} \text{NC}_i + \text{ALK}^{\text{OX}} \right) \cdot k_i \cdot \text{POC}_i(z) \quad (30)$$

565

2. Denitrification or nitrogenous zone ( $z_{\text{ox}} < z \leq z_{\text{NO}_3}$ )

$$\frac{\partial \text{ALK}^{II}}{\partial t} = 0 = D_{\text{ALK}} \frac{\partial^2 \text{ALK}^{II}}{\partial z^2} - w \frac{\partial \text{ALK}^{II}}{\partial z} + \frac{1-\phi}{\phi} \cdot \sum_i \text{ALK}^{\text{DEN}} \cdot k_i \cdot \text{POC}_i(z) \quad (31)$$

3. Sulfidic zone ( $z_{\text{NO}_3} < z \leq z_{\text{SO}_4}$ )

$$570 \quad \frac{\partial \text{ALK}^{III}}{\partial t} = 0 = D_{\text{ALK}} \frac{\partial^2 \text{ALK}^{III}}{\partial z^2} - w \frac{\partial \text{ALK}^{III}}{\partial z} + \frac{1-\phi}{\phi} \cdot \sum_i \text{ALK}^{\text{SUL}} \cdot k_i \cdot \text{POC}_i(z) \quad (32)$$

4. Methanic zone ( $z_{\text{SO}_4} < z \leq z_{\infty}$ )

$$\frac{\partial \text{ALK}^{IV}}{\partial t} = 0 = D_{\text{ALK}} \frac{\partial^2 \text{ALK}^{IV}}{\partial z^2} - w \frac{\partial \text{ALK}^{IV}}{\partial z} + \frac{1-\phi}{\phi} \cdot \sum_i \text{ALK}^{\text{MET}} \cdot k_i \cdot \text{POC}_i(z) \quad (33)$$

575 where  $D_{\text{ALK}}$  denotes the diffusion coefficient for alkalinity which depends on the bioturbation status of the respective geochemical zone. Integration of Eq. (30) - (33) yields the analytical solution and Table 8 summarises the boundary conditions applied in OMEN-SED. A Dirichlet boundary condition is applied at the sediment-water interface. The decrease of alkalinity due to oxidation of reduced species produced in the anoxic zones (with stoichiometry  $\text{ALK}^{\text{NIT}}$  and  $\text{ALK}^{\text{H}_2\text{S}}$ ) is implicitly taken into account through the flux boundary condition at  $z_{\text{ox}}$  (Table 8 Eq. 5). Furthermore, the oxidation of methane by sulfate reduction increases alkalinity with stoichiometry  $\text{ALK}^{\text{AOM}}$  which is accounted for through the flux boundary condition at  $z_{\text{SO}_4}$  (Table 8 Eq. 9). At the lower boundary  $z_{\infty}$  a zero flux condition is applied.

### 2.3 Determination of Integration Constants

585 The integration constants of all general analytical solutions derived above change in response to changing boundary conditions. Thus, OMEN-SED has to re-determine integration constants for each dynamic zone (i.e.  $z_{\text{ox}}, z_{\text{bio}}, z_{\text{NO}_3}$  and  $z_{\text{SO}_4}$ ) at every time step. The bioturbation boundary poses a particular challenge as it can theoretically occur in any of the dynamic geochemical zones (compare Fig. 3). Therefore, in order to generalise and simplify this recurring boundary matching problem, 590 an independent algorithm is implemented (rather than using a fully-worked-out algebraic solution). The algorithm only ever has to solve a two-simultaneous-equation problem.

#### 2.3.1 Generic Boundary Condition Matching (GBCM)

As discussed in Section 2.1, the solution of the general steady-state transport-reaction equation (Eq. (3)) for a generic tracer  $C$  is of the general form:

$$595 \quad C(z) = A \exp(az) + B \exp(bz) + \sum_j \frac{\alpha_j}{D\beta_j^2 - w\beta_j - k} \cdot \exp(-\beta_j z) + \frac{Q}{k} \quad (34)$$

and can therefore be expressed as:

$$C(z) = A \cdot E(z) + B \cdot F(z) + G(z) \quad (35) \quad 6.121$$

**DH:** Should it be  
 $D\beta_i^2 + w\beta_i - k$  in the  
denom. - see Boudreau  
(1997) Exp 6-13 Eq.

**Table 8.** Boundary conditions for alkalinity. For the boundaries we define:  $z_-^- := \lim_{h \rightarrow 0} (z_- - h)$  and  $z_-^+ := \lim_{h \rightarrow 0} (z_- + h)$ .

Boundary	Condition	
$z = 0$	known concentration	1) $\text{ALK}(0) = \text{ALK}_0$
$z = z_{\text{bio}}$	continuity	2) $\text{ALK}(z_{\text{bio}}^-) = \text{ALK}(z_{\text{bio}}^+)$
	flux	3) $-(D_{\text{ALK},0} + D_{\text{bio}}) \cdot \frac{\partial \text{ALK}}{\partial z}  _{z_{\text{bio}}^-} = -D_{\text{ALK},0} \cdot \frac{\partial \text{ALK}}{\partial z}  _{z_{\text{bio}}^+}$
$z = z_{\text{ox}}$	continuity	4) $\text{ALK}(z_{\text{ox}}^-) = \text{ALK}(z_{\text{ox}}^+)$
	flux	5) $-D_{\text{ALK}} \cdot \frac{\partial \text{ALK}}{\partial z}  _{z_{\text{ox}}^-} + F_{\text{ALK}}(z_{\text{ox}}) = -D_{\text{ALK}} \cdot \frac{\partial \text{ALK}}{\partial z}  _{z_{\text{ox}}^+}$ $F_{\text{ALK}}(z_{\text{ox}}) = \frac{1-\phi}{\phi} \cdot \left( \text{ALK}^{\text{H}_2\text{S}} \cdot \gamma_{\text{H}_2\text{S}} \int_{z_{\text{NO}_3}}^{\text{SO}_4} \sum_i \text{SO}_4 \cdot k_i \cdot \text{POC}_i dz \right) + \frac{1-\phi}{\phi} \cdot \left( \text{ALK}^{\text{NIT}} \frac{\gamma_{\text{NH}_4}}{1+k_{\text{NH}_4}} \int_{z_{\text{NO}_3}}^{\infty} \sum_i \text{NC}_i \cdot k_i \cdot \text{POC}_i dz \right)$
	where:	
$z = z_{\text{NO}_3}$	continuity	6) $\text{ALK}(z_{\text{NO}_3}^-) = \text{ALK}(z_{\text{NO}_3}^+)$
	flux	7) $-D_{\text{ALK}} \cdot \frac{\partial \text{ALK}}{\partial z}  _{z_{\text{NO}_3}^-} = -D_{\text{ALK}} \cdot \frac{\partial \text{ALK}}{\partial z}  _{z_{\text{NO}_3}^+}$
$z = z_{\text{SO}_4}$	continuity	8) $\text{ALK}(z_{\text{SO}_4}^-) = \text{ALK}(z_{\text{SO}_4}^+)$
	flux (with AOM)	9) $-D_{\text{ALK}} \cdot \frac{\partial \text{ALK}}{\partial z}  _{z_{\text{SO}_4}^-} + F_{\text{ALK}}(z_{\text{SO}_4}) = -D_{\text{ALK}} \cdot \frac{\partial \text{ALK}}{\partial z}  _{z_{\text{SO}_4}^+}$ $F_{\text{ALK}}(z_{\text{SO}_4}) = \frac{1-\phi}{\phi} \cdot \left( \text{ALK}^{\text{AOM}} \gamma_{\text{CH}_4} \cdot \int_{z_{\text{SO}_4}}^{\infty} \sum_i k_i \cdot \text{POC}_i dz \right)$
	where:	
$z = z_\infty$	zero ALK flux	10) $\frac{\partial \text{ALK}}{\partial z}  _{z_\infty} = 0$

600 where  $E(z)$ ,  $F(z)$  are the homogeneous solutions of the ODE,  $G(z)$  the particular integral (collectively called the basis functions), and  $A$ ,  $B$  are the integration constants that must be determined with the boundary conditions (compare Fig. 3 for the whole sediment column).

Each boundary matching problem involves matching continuity and flux for the two solutions of the respective reaction-transport equation above,  $C_U(z)$  (= 'upper'), and below,  $C_L(z)$  (= 'lower'),  
605 the dynamic boundary at  $z = z_b$ :

$$C_U(z) = A_U \cdot E_U(z) + B_U \cdot F_U(z) + G_U(z) \quad (36)$$

$$C_L(z) = A_L \cdot E_L(z) + B_L \cdot F_L(z) + G_L(z). \quad (37)$$

OMEN-SED generally applies concentration continuity and flux boundary conditions at its internal,  
610 dynamic boundaries:

Continuity (where for generality we allow a discontinuity  $V_b$ )

$$C_U(z_b) = C_L(z_b) + V_b \quad (38)$$

Flux

$$615 D_U C'_U(z_b) + w C_U(z_b) = D_L C'_L(z_b) + w C_L(z_b) + F_b \quad (39)$$

where  $w$  is advection,  $D$  are the diffusion coefficients and  $F_b$  is any flux discontinuity.

Substituting the general ODE solutions (36), (37), the boundary conditions can be represented as

two equations connecting the four integration constants:

$$\begin{pmatrix} E_U & F_U \\ D_U E'_U & D_U F'_U \end{pmatrix} \begin{pmatrix} A_U \\ B_U \end{pmatrix} = \begin{pmatrix} E_L & F_L \\ D_L E'_L & D_L F'_L \end{pmatrix} \begin{pmatrix} A_L \\ B_L \end{pmatrix} + \begin{pmatrix} G_L - G_U + V_b \\ D_L G'_L - D_U G'_U + F_b - wV_b \end{pmatrix} \quad (40)$$

620

where the ODE solutions  $E$ ,  $F$ ,  $G$  are all evaluated at  $z_b$ .

Equation (40) can now be solved to give  $A_U$  and  $B_U$  as a function of the integration constants from the layer below ( $A_L$  and  $B_L$ ), thereby constructing a piecewise solution for both layers, with just two integration constants (this is implemented in the function **benthic\_utils.matchsoln** of OMEN-

625 SED):

$$\begin{pmatrix} A_U \\ B_U \end{pmatrix} = \begin{pmatrix} c_1 & c_2 \\ c_3 & c_4 \end{pmatrix} \begin{pmatrix} A_L \\ B_L \end{pmatrix} + \begin{pmatrix} d_1 \\ d_2 \end{pmatrix}. \quad (41)$$

Using Eq. (41),  $C_U(z)$  in (36) can now be rewritten as a function of  $A_L$  and  $B_L$  (implemented in **benthic\_utils.xformsoln**):

$$C_U(z) = (c_1 A_L + c_2 B_L + d_1) \cdot E_U(z) + (c_3 A_L + c_4 B_L + d_2) \cdot F_U(z) + G_U(z) \quad (42)$$

630 and hence define the “transformed” basis functions  $E_U^*(z)$ ,  $F_U^*(z)$ ,  $G_U^*(z)$  such that:

$$C_U(z) = A_L \cdot E_U^*(z) + B_L \cdot F_U^*(z) + G_U^*(z) \quad (43)$$

where

$$\begin{aligned} E_U^*(z) &= c_1 E_U(z) + c_3 F_U(z) \\ F_U^*(z) &= c_2 E_U(z) + c_4 F_U(z) \end{aligned} \quad (44)$$

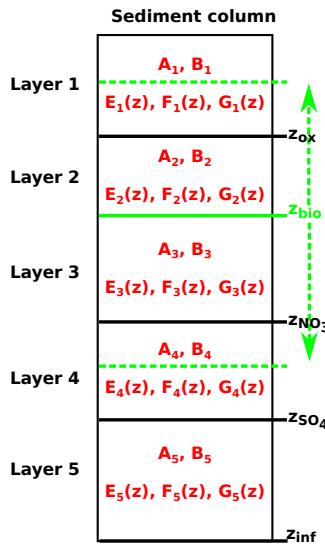

635  $G_U^*(z) = G_U(z) + d_1 E_U(z) + d_2 F_U(z)$

Equations (41), (43) and (44) can now be consecutively applied for each of the dynamic biogeochemical zone boundaries, starting at the bottom of the sediment column. The net result is a piecewise solution of the whole sediment column with just two integration constants (coming from 640 the lowest layer), which can then be solved for by applying the boundary conditions at the sediment-water interface and the bottom of the sediments .

### 2.3.2 Abstracting out the bioturbation boundary

The bioturbation boundary affects the diffusion coefficient of the modelled solutes, as well as the conservation equation of organic matter (and thereby the exact form of each reaction-transport equa-

645 tion). This boundary is particularly inconvenient as it can, in principle, occur in the middle of any of the dynamically shifting biogeochemical zones and therefore generates multiple cases (compare

**Figure 3.** Schematic of the generic boundary condition matching (GBCM) problem. Showing the resulting integration constants ( $A_i, B_i$ ) and ODE solutions ( $E_i, F_i, G_i$ ) for the different sediment layers and the variable bioturbation boundary.

Fig. 3). The GBCM algorithm described above is thus not only used to construct a piecewise solution of the whole sediment column, but also to abstract out the bioturbation boundary. For each  
650 bioturbation zone the "bioturbation-status" is initially tested (i.e. fully bioturbated, fully non-  
bioturbated, or crossing the bioturbation boundary). Therefore, the upper and lower boundaries for  
the different zones (e.g. for the nitrogenous zone:  $z_U = z_{\text{Ox}}$ ,  $z_L = z_{\text{NO}_3}$ ), as well as the respec-  
tive reactive terms and diffusion coefficients (bioturbated and non-bioturbated) are passed over to  
the routine **zTOC.prepfg\_I12** where the bioturbations-status is determined. In case the bioturba-  
tion depth is located within this zone (i.e.  $z_U < z_{\text{bio}} < z_L$ ) a piecewise solution for this layer is  
655 constructed. Therefore, the reactive terms and diffusion coefficients are handed over to the rou-  
tines **zTOC.calcfg\_I1** and **zTOC.calcfg\_I2** which calculate the basis functions ( $E_U, F_U, G_U$  and  
 $E_L, F_L, G_L$ ) and their derivatives for the bioturbated and the non-bioturbated part of this specific  
geochemical zone. The concentration and flux for both solutions at  $z_{\text{bio}}$  are matched and the coef-  
ficients  $c_1, c_2, c_3, c_4, d_1, d_2$  (as in Eq. (41)) are calculated by the routine **benthic\_utils.matchsoln**.  
660 These coefficients and the "bioturbation-status" of the layer are passed back to the main GBCM  
algorithm where they can be used by the routine **benthic\_utils.xformsoln** to calculate the "trans-  
formed" basis functions ( $E_U^*(z), F_U^*(z), G_U^*(z)$ ) such that both layers are expressed in the same  
basis (compare Eq. (42 - 44)).

For instance, in the case of sulfate, **zTOC.prepfg\_I12** is called three times before the actual  
665 profile is calculated (once per zone: oxic, nitrogenous, sulfidic) and hands back the information  
about the "bioturbation-status" of the three layers and the coefficients  $c_1, c_2, c_3, c_4, d_1, d_2$  for the

biogeochemical zone including the bioturbation depth. When calculating the complete piecewise solution for the sediment column, this information is passed to the function **zTOC.calcfg\_I12** which sorts out the correct solution type to use. The main GBCM algorithm therefore never needs to know  
 670 whether it is dealing with a piecewise solution (i.e. matched across the bioturbation boundary) or a “simple” solution (i.e. the layer is fully bioturbated or fully non-bioturbated).

## 2.4 Model Parameters

The following section provides a summary of global relationships used to constrain reaction and transport parameters in OMEN-SED. Table 9 synthesises sediment and transport parameters, while  
 675 table 10 provides an overview of all biogeochemical parameters used in OMEN-SED.

### 2.4.1 Transport Parameters

The burial of sediments and porewater is directly related to the accumulation of new material on the seafloor (i.e. sedimentation, Burdige, 2006). This results in a downward advective flux of older sediment material and porewater in relation to the sediment-water interface. When coupled to an  
 680 ocean model, its sedimentation flux can be readily used in OMEN-SED. The stand-alone version of OMEN-SED uses the empirical global relationship between sediment accumulation rate ( $\text{cm yr}^{-1}$ ) and seafloor depth (m) of Middelburg et al. (1997):

$$w = 3.3 \cdot 10^{-0.87478367 - 0.00043512 \cdot \text{depth}}, \quad (45)$$

As mentioned before (Sec. 2.1), the diffusion coefficient of species  $i$  is calculated as  $D_i = D_{i,0} +$   
 685  $D_{\text{bio}} = D_{\text{mol},i} \cdot f_{ir} + D_{\text{bio}}$  for dissolved species and  $D_i = D_{\text{bio}}$  for solid species. The bioturbation coefficient  $D_{\text{bio}}$  ( $\text{cm}^2 \text{ yr}^{-1}$ ) is constant in the bioturbated zone and also follows the empirical relationship by Middelburg et al. (1997):

$$D_{\text{bio}} = 5.2 \cdot 10^{0.76241122 - 0.00039724 \cdot \text{depth}} \quad (46)$$

Observations indicate that bioturbation is largely restricted to the upper 10 cm of the sediments and is  
 690 only marginally related to seafloor depth (e.g. Boudreau, 1998; Teal et al., 2010). Therefore, OMEN-SED imposes a globally invariant bioturbation depth  $z_{\text{bio}}$  of 10 cm. In case the bottom water oxygen concentration is below 5 nanomole  $\text{cm}^{-3}$  infaunal activity is assumed to cease and  $z_{\text{bio}} = 0.01 \text{ cm}$ . We choose a low value unequal to zero in order to simplify the implementation of the model as this ensures the same method to solve the conservation equations can be used.

**SA:** need to explain why not 0; **DH:** Decent explanation?

695 Bioirrigation can enhance the molecular diffusion coefficient  $D_{i,0} = D_{\text{mol},i} \cdot f_{ir}$  (Soetaert et al., 1996a). However, here we do not consider this effect as it is difficult to constrain on geological timescales and set  $f_{ir}$  to a constant value of 1. The specific molecular diffusion coefficients  $D_{\text{mol},i}$  are corrected for sediment porosity  $\phi$ , tortuosity  $F$  and are linearly interpolated for an ambient temperature  $T$  using zero-degree coefficients  $D_i^0$  and temperature-dependent diffusion coefficients  $D_i^T$

700 (compare Gypens et al., 2008):

$$D_{\text{mol},i} = (D_i^0 + D_i^T \cdot T) \cdot \frac{1}{\phi \cdot F}.$$

Tortuosity can be expressed in terms of porosity as  $F = \frac{1}{\phi^m}$  (Ullman and Aller, 1982) with the exponent  $m$  varying according to the type of sediment (here we use  $m=3$ ). Values for  $D_i^T$  and  $D_i^0$  are summarised in Table 9 and are adapted from Li and Gregory (1974), Schulz (2006) and Gypens  
705 et al. (2008).

## 2.4.2 Reaction Parameters and Stoichiometries

**difficult to find a structure, I'd adapt to the order in the table and groups -as much as possible- according to chemical species, Also ALL parameters must be described and justified. Let me take care of this section:** The first-order organic matter degradation constants of compound class  $i$ ,  
710  $k_i$  ( $\text{yr}^{-1}$ ), are assumed invariant along the sediment column and therefore independent of the nature of the terminal electron acceptor. The rate constants can be altered manually to fit observed sediment profiles (compare Section 5.1) or related to a master variable (e.g. sedimentation rate or POC-flux) provided by a coupled Earth system model (compare Section ?? and 5.3). **until here, also need to mention  $f_i$**  Organic matter degradation consumes oxygen with a 1:1 stoichiometry.

715 **N-related parameters: N/C, NO<sub>3</sub>C, NH4, adsorption coefficient, gamma- explain nitrification**

**SO<sub>4</sub>-H<sub>2</sub>S related parameters: SO<sub>4</sub>C , gamma, AOM** reduction of 1 mol organic matter additionally produces SO<sub>4</sub>C =  $\frac{138}{212}$  mol of hydrogen sulfide

**methane: MC, AOM** MC = 0.5 mol of methane.

The rate constants sorption of PO<sub>4</sub> to Fe oxides,  $k_s$ , release of PO<sub>4</sub> from Fe-bound P due to Fe-  
720 oxide reduction  $k_m$  and authigenic CFA precipitation  $k_a$  are constrained on the basis of ???. The pore water equilibrium concentrations for P sorption and CFA precipitation (PO<sub>4</sub><sup>s</sup>, PO<sub>4</sub><sup>a</sup>) and the asymptotic concentration for Fe-bound P (M<sup>∞</sup>) are taken from Palastanga et al. (2011). The phosphorus to carbon ratio represents the composition of organic matter and is chosen as ?? based on ??.

725 See Table 10 for a complete summary of the parameters and their values.

## 3 Methodology for sensitivity and case studies

### 3.1 Sensitivity study

To validate our model approach an extensive sensitivity analysis for the most important model parameters is performed with the stand-alone version of OMEN-SED and resulting sediment-water  
730 interface fluxes are compared with a global database (Section 4). Model parameters implicitly account for processes that are not explicitly resolved. Therefore, model parameters are notoriously difficult to constrain and a source of uncertainty for numerical and analytical models. A comprehen-

**Table 9.** Sediment characteristics and transport parameters. **TODO: PO4 adsorption coefficients okay?**

Parameter	Unit	Value	Description/Source
$\rho_{\text{sed}}$	$\text{g cm}^{-3}$	2.6	Sediment density
$w$	$\text{cm yr}^{-1}$	Fct. of seafloor depth or from ESM	Advection/Sediment accumulation rate (Middelburg et al., 1997)
$z_{\text{bio}}$	cm	10 or 0.01	Bioturbation depth (Boudreau, 1998; Teal et al., 2010)
$D_{\text{bio}}$	$\text{cm}^2 \text{yr}^{-1}$	Fct. of seafloor depth	Bioturbation coefficient (Middelburg et al., 1997)
$\phi$	-	0.85	Porosity
F	-	$\frac{1}{\phi^m}$	Tortuosity, here m=3
$f_{ir}$	-	1	Irrigation factor
<b>Adsorption coefficients</b>			
$K_{\text{NH}_4}$	-	1.3	$\text{NH}_4$ adsorption coefficient, (see Wang and Van Cappellen, 1996)
$K_{\text{PO}_4}^{\text{ox}}$	-	200.0	$\text{PO}_4$ adsorption coefficient (oxic), (see Slomp et al., 1998)
$K_{\text{PO}_4}^{\text{anox}}$	-	1.3	$\text{PO}_4$ adsorption coefficient (anoxic), (see Slomp et al., 1998)
<b>Diffusion coefficients</b> (Li and Gregory, 1974; Schulz, 2006; Gypens et al., 2008)			
$D_{\text{O}_2}^0$	$\text{cm}^2 \text{yr}^{-1}$	348.62	Molecular diffusion coefficient of oxygen at 0°C
$D_{\text{O}_2}^T$	$\text{cm}^2 \text{yr}^{-1} \text{°C}^{-1}$	14.09	Diffusion coefficient for linear temp. dependence of oxygen
$D_{\text{NO}_3}^0$	$\text{cm}^2 \text{yr}^{-1}$	308.42	Molecular diffusion coefficient of nitrate at 0°C
$D_{\text{NO}_3}^T$	$\text{cm}^2 \text{yr}^{-1} \text{°C}^{-1}$	12.26	Diffusion coefficient for linear temp. dependence of nitrate
$D_{\text{NH}_4}^0$	$\text{cm}^2 \text{yr}^{-1}$	309.05	Molecular diffusion coefficient of ammonium at 0°C
$D_{\text{NH}_4}^T$	$\text{cm}^2 \text{yr}^{-1} \text{°C}^{-1}$	12.26	Diffusion coefficient for linear temp. dependence of ammonium
$D_{\text{SO}_4}^0$	$\text{cm}^2 \text{yr}^{-1}$	157.68	Molecular diffusion coefficient of sulfate at 0°C
$D_{\text{SO}_4}^T$	$\text{cm}^2 \text{yr}^{-1} \text{°C}^{-1}$	7.88	Diffusion coefficient for linear temp. dependence of sulfate
$D_{\text{H}_2\text{S}}^0$	$\text{cm}^2 \text{yr}^{-1}$	307.48	Molecular diffusion coefficient of sulfide at 0°C
$D_{\text{H}_2\text{S}}^T$	$\text{cm}^2 \text{yr}^{-1} \text{°C}^{-1}$	9.64	Diffusion coefficient for linear temp. dependence of sulfide
$D_{\text{PO}_4}^0$	$\text{cm}^2 \text{yr}^{-1}$	112.91	Molecular diffusion coefficient of phosphate at 0°C
$D_{\text{PO}_4}^T$	$\text{cm}^2 \text{yr}^{-1} \text{°C}^{-1}$	5.59	Diffusion coefficient for linear temp. dependence of phosphate
$D_{\text{DIC}}^0$	$\text{cm}^2 \text{yr}^{-1}$	151.69	Molecular diffusion coefficient of DIC at 0°C
$D_{\text{DIC}}^T$	$\text{cm}^2 \text{yr}^{-1} \text{°C}^{-1}$	7.93	Diffusion coefficient for linear temp. dependence of DIC
$D_{\text{ALK}}^0$	$\text{cm}^2 \text{yr}^{-1}$	151.69	Molecular diffusion coefficient of ALK at 0°C
$D_{\text{ALK}}^T$	$\text{cm}^2 \text{yr}^{-1} \text{°C}^{-1}$	7.93	Diffusion coefficient for linear temp. dependence of ALK
Note: DIC and ALK coefficients are the values of $\text{HCO}_3^-$ from Schulz (2006).			

**Table 10.** Values for biogeochemical parameters used in OMEN-SED. The variables  $x$ ,  $y$  and  $z$  denote the atomic ratio of carbon, nitrogen and phosphorus of the degrading organic matter (here set to  $C : N : P = 106 : 16 : 1$ ). **P related coefficients okay?**

hensive sensitivity analysis (SA) can help quantify this uncertainty and identify the most sensitive parameters. More specifically, sensitivity analysis is used to investigate how the variations in the outputs ( $y_1, \dots, y_N$ ) of a model can be attributed to variations in the different input parameters ( $x_1, \dots, x_M$ , Pianosi et al., 2016). Different types of sensitivity indices, which quantify this relative influence with a scalar  $S_i$ , can be calculated, ranging from simple one-at-a-time methods to statistical evaluations of the output distribution (e.g. variance-based or density-based approaches Pianosi et al., 2016). The latter indices take values between zero and one ( $S_i \in [0, 1]$ ), where zero indicates a non-influential parameter and a higher value a more influential parameter. Here, we use SA mainly to identify which parameters have the largest impact on the different model outputs and therefore require careful calibration. As the probability density functions of our model outputs (i.e. the resulting SWI-fluxes) are generally highly-skewed towards extreme organic matter degradation rates (not shown) variance-based sensitivity indices may not be a suitable proxy for output uncertainty (Pianosi et al., 2016). Hence we employ the novel density-based PAWN method by Pianosi and Wagener (2015) which considers the entire conditional and unconditional Cumulative Distribution Function (CDF) of the model output rather than its variance only. The sensitivity index of parameter  $i$  is measured by the distance between the two CDFs, i.e.

$$S_i = \max_{x_i} \max_y |F_y(y) - F_{y|x_i}(y)| \quad (47)$$

where  $F_y(y)$  is the unconditional CDF of the output  $y$  and  $F_{y|x_i}(y)$  represents the conditional CDF when the  $i$ -th parameter is fixed to the conditioning value  $x_i$ . For a more detailed description of the method we refer the interested reader to Pianosi and Wagener (2015).

Due to the model complexity it is impossible to compute the sensitivity indices analytically therefore they are approximated from a Latin-Hypercube sampling of parameter inputs and calculated outputs. The PAWN method, as implemented within the Sensitivity Analysis for Everyone (SAFE) matlab toolbox (Pianosi et al., 2015), is used to investigate 11 model parameters for ranges as specified in Table 11. Sensitivity indices for all resulting SWI-fluxes for two idealised sediment conditions (i.e. anoxic at 400 m and oxic at 4000 m, see Table 12) are calculated. We use 200 samples to estimate the unconditional CDF, 100 samples to estimate the conditional CDFs and 10 conditioning points, thus  $200 + 100 \cdot 10 \cdot 11 = 11,200$  evaluations are performed for each sediment condition. The resulting indices are then translated into a color code and summarised in a pattern plot to simplify comparison (Fig. 6).

### 3.2 Case study: Stand-alone simulations of sediment cores

In order to illustrate the capabilities of OMEN-SED, comprehensive datasets from the Santa Barbara Basin (Reimers et al., 1996), as well as from the Iberian margin and the Nazaré Canyon (Epping et al., 2002) are modelled. Section 5.1 compares modelled profiles with measured pore water data from different depths including the continental shelf (108 m) and the lower slope (2213 m) located

**SA:** needs polishing

**DH:** Better like this?

**Table 11.** Range of model parameters used for sensitivity analysis of model predicted output.

Parameter	Description	Units	Minimum	Maximum	Source

at the Iberian margin, the upper slope (585 m) from the Santa Barbara Basin, and a deep sea site (4298 m) in the Nazaré Canyon. The Santa Barbara Basin is characterised by anoxic bottom waters,  
770 high POC concentrations and varved sediments (Reimers et al., 1990), therefore the depth of bioturbation in OMEN-SED is restricted to the upper 0.01 cm. In the uppermost sediments iron(III) hydroxides are reduced, releasing  $\text{Fe}^{2+}$  which reacts with sulfide to form iron sulfides. Thus, the Fe cycle exerts a strong control on sulfide concentrations in the sediments of this basin (Reimers et al., 1996). In addition, the sediments are generally supersaturated with respect to carbonate fluorapatite  
775 by and below 2 cm (Reimers et al., 1996). The Iberian margin, situated in the northeastern Atlantic, generally belongs to the more productive regions of the global ocean (Longhurst et al., 1995), however, seasonal changes in upwelling creates a strong temporal variability in primary productivity and organic carbon deposition and submarine canyons in this area (like the Nazaré Canyon) may deliver organic carbon from the shelf to the ocean interior (van Weering et al., 2002; Epping et al., 2002).  
780 For a more detailed description of the study areas and the experimental work, the interested reader is referred to the Reimers et al. (1996) and Epping et al. (2002).

**Table 13.** Model boundary conditions for the sampling stations in Figure 8. (For all sites DIC bottom water concentration of 2,400 nanomole cm<sup>-3</sup> is assumed.)

In OMEN-SED sediment characteristics and boundary conditions are set to the observed values where available (Table 13). Other sediment characteristics (e.g. sedimentation rate, porosity, density), stoichiometric factors and secondary reaction parameters are set to the default value (see Table 785 9 and 10). Organic matter is modelled as two fractions, with different first-order degradation rate constants. The POC and pore water profiles were fitted by optimizing the POC partitioning into the fast and slow degrading pool and their respective first-order degradation rate constants (priority is given to reproduce the POC and O<sub>2</sub> profiles). For phosphorus the equilibrium concentration for authigenic P formation (PO<sub>4</sub><sup>a</sup>) was adjusted to fit the PO<sub>4</sub> concentration at  $z_\infty$ .

### 790 3.3 Case study: Stand-alone simulations of global ocean transect

In section 5.2 it is tested to which degree OMEN-SED is capable of capturing the dynamics of organic matter degradation pathways and related TEA-fluxes as simulated with a complete, numerical diagenetic model. Therefore, we reproduce the simulations of typical conditions along a global ocean hypsometry of Thullner et al. (2009) and compare our modeled TEA-fluxes with the results of 795 the complete model and observations from Middelburg et al. (1996). To explore the global remineralisation of OM in the seafloor Thullner et al. (2009) quantified various diagenetic processes using the Biogeochemical Reaction Network Simulator (BRNS, Aguilera et al., 2005), a flexible simulation environment suitable for reactive transport simulations of complex biogeochemical problems (e.g. Jourabchi et al., 2005; Thullner et al., 2005). Thullner et al. (2009) used seafloor depth (SFD) as the 800 master variable and calculated model parameters, such as  $w$ ,  $D_{bio}$  and  $\phi$ , from existing empirical relationships (e.g. Van Cappellen and Wang, 1995; Middelburg et al., 1997). Organic matter degra-

SA: needs polishing

DH: Better like this?

dation is described with a 1-G approach, thus assuming a single pool of organic matter of uniform reactivity. The first order rate constant is related to the burial velocity,  $w$  (cm year $^{-1}$ ), following the empirical relationship of Boudreau (1997):

805  $k = 0.38 \cdot w^{0.59}$ . (48)

This rate constant can be assumed as the mean reactivity of the organic matter fractions which are degraded in the upper, bioturbated 10 – 20 cm of the sediments. Thus, more reactive fractions (degraded during days/weeks close to the SWI) and more refractory fractions (degraded on longer time scales deeper in the sediments) are not captured by this relationship (Boudreau, 1997). BRNS

810 simulations were performed using boundary conditions and parameters for depths representative for shelf, slope and deep sea sediments (i.e. SFD of 100m, 200m, 500m, 1000m, 2000m, 3500m and 5000m). In order to reproduce these results, OMEN-SED is configured as a 1-G model and boundary conditions and model parameters are defined as in Thullner et al. (2009, see Table 14). As OMEN-SED assumes a fixed fraction of reduced substances to be reoxidised, which exerts a large impact on 815 the resulting SWI-fluxes (compare Section 4), we perform two sets of simulations in order to show the range of possible model outputs. In the first setup 95% of the reduced substances are reoxidised (i.e.  $\gamma_{NH_4} = \gamma_{H_2S} = 0.95$ ) and in the second only 5% are reoxidised (all other model parameters and boundary conditions are equal).

### 3.4 Case Study: Coupled pre-industrial Earth system model simulations

#### 820 3.4.1 Coupling to an Earth System Model

OMEN-SED is coupled to the carbon-centric version of the “GENIE” Earth system model (cGENIE, Ridgwell et al., 2007) to illustrate the abilities of the newly developed model. The following section provides a brief description of cGENIE and the coupling procedure (Fig. 4). cGENIE is a model of Intermediate Complexity based on the efficient climate model “C-GOLDSTEIN” of Edwards and Marsh (2005), featuring a frictional-geostrophic 3D-ocean circulation model coupled to a fast Energy-Moisture Balance 2D-atmosphere together with a dynamic-thermodynamic sea-ice component. The version of cGENIE used here includes the marine geochemical cycling of carbon, oxygen, phosphorus and sulfur (Ridgwell et al., 2007), preservation of carbonates in deep-sea sediments (SEDGEM, Ridgwell and Hargreaves, 2007) and terrestrial weathering (Colbourn et al., 825 2013). The ocean model is implemented on a  $36 \times 36$  equal-area horizontal grid with 16 vertical levels using the pre-industrial continental configuration and bathymetry as in Archer et al. (2009). A finer grid ( $72 \times 72$ ) is used for the sediments. Instead of completely degrading POC at the seafloor, OMEN-SED is called by SEDGEM for each wet ocean grid point. Depending on the overlying biogeochemical ocean model, processes can be included or excluded in OMEN-SED and stoichiometric 830 factors need to be adjusted to ensure preservation of mass. As nitrogen is not modelled explicitly in the employed cGENIE configuration, related stoichiometries in OMEN-SED are set to zero (i.e.

**Figure 4.** Schematic of the relationship between OMEN-SED and cGENIE. Arrows and accompanied text represent the information transferred between models.

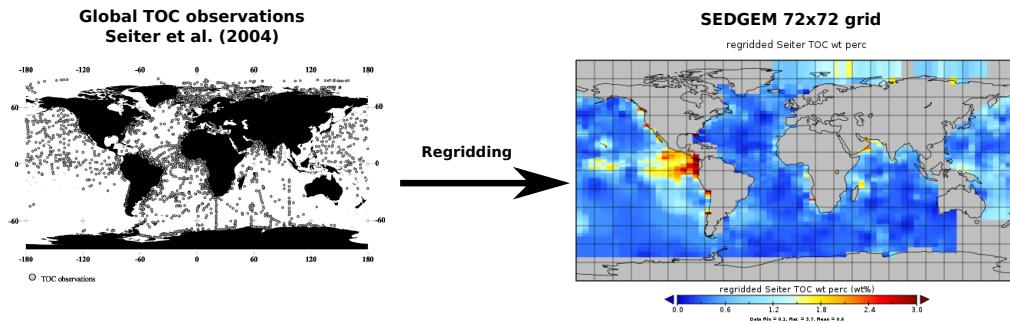

NC<sub>i</sub>, ALK<sup>NIT</sup> and ALK<sup>DEN</sup>). cGENIE, however, implicitly includes the effects of NH<sub>4</sub> release and its complete nitrification on alkalinity and neglects the impact of P release. Therefore, alkalinity stoichiometries from aerobic degradation and sulfate reduction are changed to ALK<sup>OX</sup> = -16/106  
840 and ALK<sup>SUL</sup> = 122/106 (compare to default in Table 10).

Several biogeochemical tracers and parameters are transferred from SEDGEM to OMEN-SED and have to be converted into the required units. Bottom water concentrations of solutes are converted from mol kg<sup>-1</sup> to mol cm<sup>-3</sup> and the depositional flux of POC (POC<sub>flux</sub>) is converted from cm<sup>3</sup> cm<sup>-2</sup> yr<sup>-1</sup> to mol cm<sup>-2</sup> yr<sup>-1</sup> assuming an average density of POC of 1.0 cm<sup>3</sup> g<sup>-1</sup>. Other parameters used from cGENIE are seafloor depth, local temperature and the partitioning of bulk POC into the slower and faster degrading pool (as cGENIE represents a labile and a refractory POC fraction, see Ridgwell et al., 2007). The advection/burial rate (*w*) is generally taken from cGENIE, however, a minimum value of *w* = 0.5 cm kyr<sup>-1</sup> is imposed as OMEN-SED tends to be unstable for lower values. The bulk POC<sub>flux</sub> is separated into the labile and refractory component and the  
845 routine to find the steady-state solution for POC is called. Here, the two POC depositional fluxes are first converted into SWI concentrations (in mol cm<sup>-3</sup>) by solving Eq. (2) for z=0. OMEN-SED then computes the fraction of POC preserved in the sediment at a depth of 100 cm (POC<sub>pres</sub>) and subsequently calls the routines to find the steady-state solutions for the solute substances. Finally,  
850 POC<sub>pres</sub> and the SWI-fluxes of solutes (in mol cm<sup>-2</sup> yr<sup>-1</sup>) are returned to cGENIE. In case no POC is deposited on the seafloor (i.e. POC<sub>flux</sub> = 0), OMEN-SED is not called and the SWI-fluxes of solutes and POC<sub>pres</sub> are set to zero. In order to reduce memory requirements the sediment profiles (e.g. as shown in Fig. 8) are not calculated in the FORTRAN version of OMEN-SED, however, the boundary conditions are saved at the end of the experiment and sediment profiles for specific grid-cells, ocean basins and ocean transects can be plotted using the stand-alone MATLAB version of  
855 OMEN-SED

### 3.4.2 Coupled pre-industrial simulations

All simulations presented in section 5.3 are run for 20,000 years to steady-state and OMEN-SED is called for each grid-cell in every time step, feeding back the resulting SWI-fluxes and the fraction of POC preserved in the sediments to cGENIE. As shown in our sensitivity analysis (Section 4) and  
865 discussed by Arndt et al. (2013) the degradation rate constants for OM (*k<sub>i</sub>*) are the most influential parameters and strongly determine the SWI-flux of redox-sensitive elements as well as the preservation of organic matter. Yet, their spatial variability is unknown at the global scale and reported rate constants can vary by almost 10 orders of magnitude (Arndt et al., 2013). Thus defining appropriate OM degradation rate constants is a major challenge and source of uncertainty for diagenetic models.  
870 The rate constants in models are either determined through profile fitting for a specific site or, for global applications, they are related to a single, readily available characteristic (or master variable) of the local environmental conditions. For instance, considerable effort has been expended to relate

the apparent rate constant for oxic and anoxic OM degradation to sedimentation rate ( $w$ ) and various empirical relations have been proposed (Toth and Lerman, 1977; Tromp et al., 1995; Boudreau, 875 1997; Stolpovsky et al., 2015). Nevertheless, these relationships are generally based on limited data sets and their global applicability is questionable (Arndt et al., 2013).

**Figure 5.** TODO: Update with new regridded observations using MATLAB. Global distribution of TOC observations ( $N=5500$ ) from the database of Seiter et al. (2004, left) and regridded observations onto the SEDGEM grid (right). Grid points without any observations are left blank (white).

In section 5.3, we test globally invariant values for the OM degradation rate constants ( $k_1, k_2$ ) as well as the empirical relationship of Boudreau (1997) which is also used in Section 5.2. The modelled mean POC weight percent (wt%) in the upper 5cm of the sediments is compared to the 880 global POC observations in surface sediments (< 5cm sediment depth) of Seiter et al. (2004). The original data field of Seiter et al. (2004) has been transformed onto the  $72 \times 72$  SEDGEM grid (Figure 5). The relationship proposed by Boudreau (1997) relates the apparent OM degradation rate constant in the bioturbated layer to the burial velocity,  $w$  (cm year $^{-1}$ ):

$$k_{\text{app}} = 0.38 \cdot w^{0.59}. \quad (49)$$

885 We assume that  $k_{\text{app}}$  represents the mean OM reactivity in the bioturbated layer and make the following assumptions in order to calculate the two degradation rate constants for OMEN-SED:

$$k_{\text{app}} = f_1 \cdot k_1 + f_2 \cdot k_2 \quad (50)$$

$$k_2 = k_1/x \quad (51)$$

890 where  $x$  describes the relation between  $k_1$  and  $k_2$  and is subject to sensitivity experiments in Section 5.3 (with values of  $x \in \{2, 4, 5, 8, 10, 25, 50, 100, 125\}$ ). As the fractions of labile and refractory OM reaching the sediments ( $f_1, f_2$ ) is known from cGENIE we can calculate  $k_1$  and  $k_2$  independently for each grid-cell. For the globally invariant degradation rate experiment in Section 5.3,  $k_2$  is systematically varied between 0.0002 and 0.005 year $^{-1}$  and the more labile OM component, described 895 by  $k_1$ , is assumed to degrade 2, 4, 5, 8, 10, 20 and 50 times faster, respectively.

## 4 Sensitivity Analysis

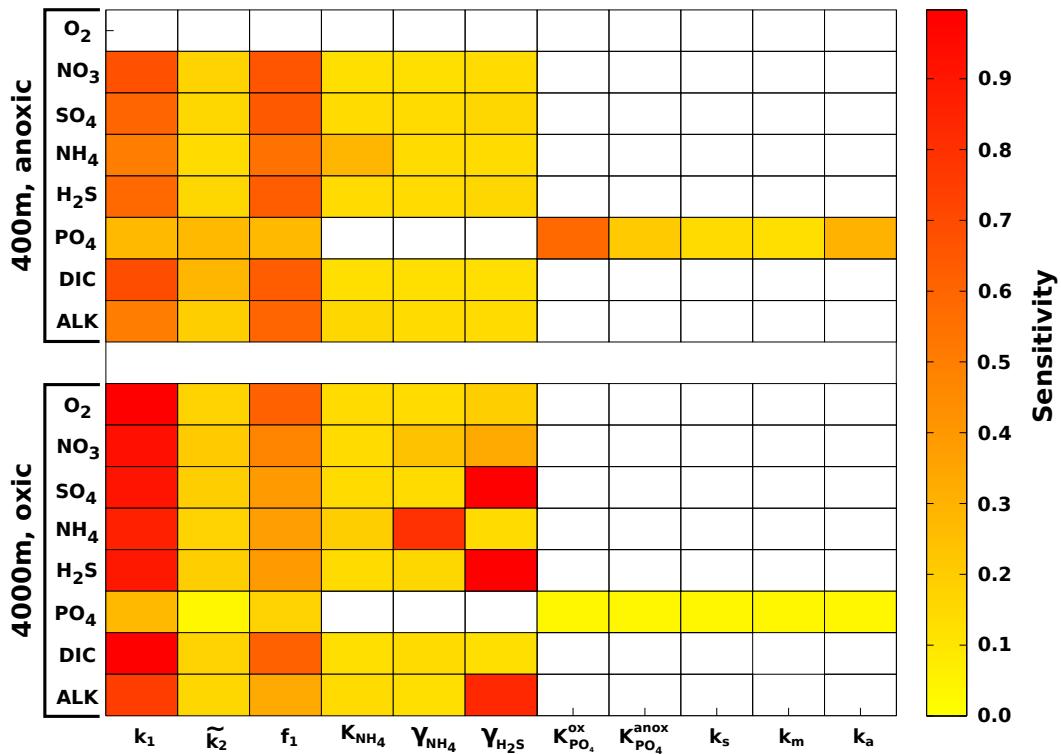

Fig. 6 summarises results of the sensitivity analysis (compare Section 3.1) as a colour map. Results indicate that the most significant parameters for all model outputs are the degradation rate constant for the labile OM part ( $k_1$ ) and the fraction of the labile pool to the total OM pool ( $f_1$ ). **also need to**  
900 **be careful how we formulate it, as you made  $k_2$  dependant on  $k_1$ . TODO: -frst shortly describe the main results, e.g. fluxes are most sensitivity to variations in OM degradation parameters, other parameters play a secondary role**  
**the describe which other parameters are red and why**  
**then describe difference odic-anoxic**  
905 **Overall: needs more critical analysis!** For the anoxic setup the secondary redox parameters (i.e.  $\gamma_{\text{NH}_4}$ ,  $\gamma_{\text{H}_2\text{S}}$ ) are essentially non-influential. Whereas in the oxic scenario, SWI-fluxes of  $\text{NH}_4$ ,  $\text{SO}_4$  and  $\text{H}_2\text{S}$  are very sensitive to changes in the secondary redox parameters. The  $\text{PO}_4$  SWI-flux appears to be insensitive (TODO: to which parameters specifically) especially for the oxic condition as the majority is absorbed to Fe-oxides. The sensitivities change if other  $\text{PO}_4$  related equilibrium  
910 concentrations  $\text{PO}_4^s$ ,  $\text{PO}_4^a$  and  $\text{M}^\infty$  are used (not shown).  
DH: explanation for small P sensitivity correct?

We further explore the sensitivity of simulated sediment-water exchange fluxes to variations in organic matter degradation parameters by varying  $k_1$ ,  $f_1$  and  $\tilde{k}_2$  while all other model parameters are set to their default values (Tables 9 and 10). For the deep sea condition we account for the presence of more refractory OM by sampling  $f_1 \in [0.02, 0.3]$ . Minimum and maximum values for  $k_1$ ,  $\tilde{k}_2$  and  
915  $f_1$  in the shallow ocean are as in Table 11. The parameter space is sampled using another Latin-Hypercube approach with sample sizes of  $N = 3500$  for each idealised sediment condition. Figure 7 summarises the results of the sensitivity study. In addition, the range of observed  $\text{O}_2$  and  $\text{NO}_3$  sediment-water interface fluxes extracted from a global database (Bohlen et al., 2012) is indicated.  
**TODO: needs a more critical analysis, what is the message you want the reader to understand**  
920 **here?** Figure 7 shows that the observed fluxes fall well in the range of SWI-fluxes calculated with OMEN-SED. Also highlighted by the emergence of colour patterns in Figure 7 A+B are the strong interactions between the amount of labile OM  $f_1$  and its degradation rate  $k_1$  for the resulting SWI-fluxes of the most powerful TEA available. In general, a higher degradation rate in combination with more labile OM available leads to a higher SWI-flux.

## 925 5 Case-studies

### 5.1 Stand-alone simulation of sediment cores

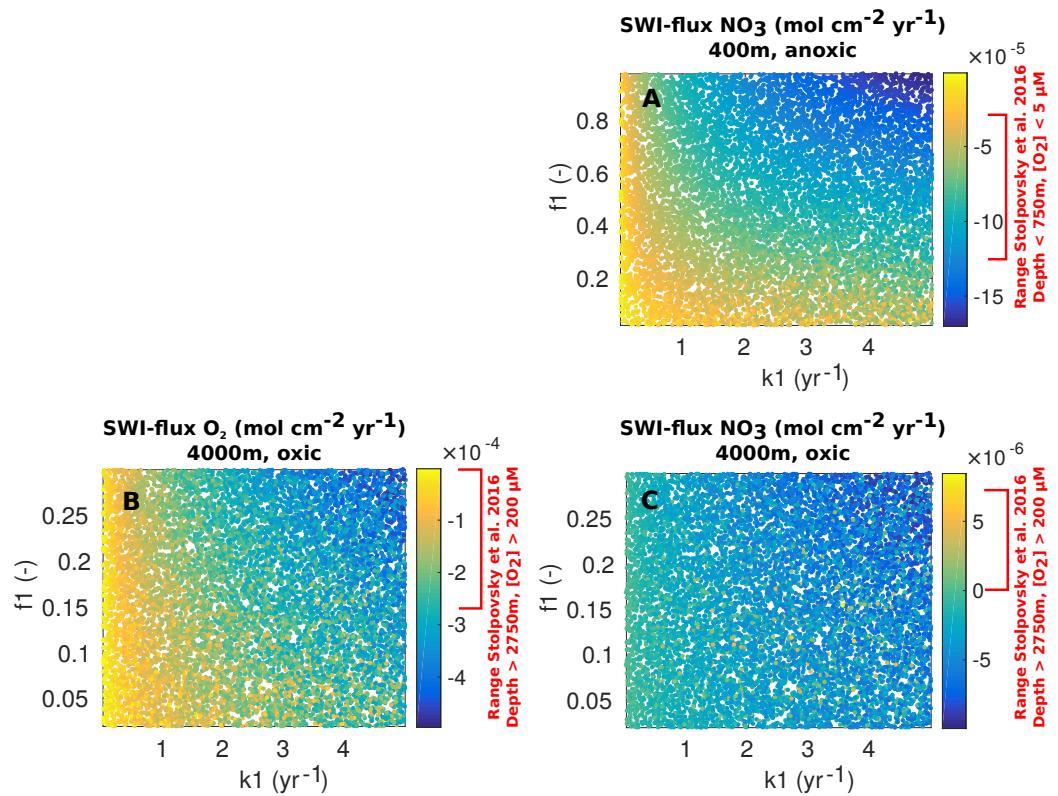

Fig. 8 compares modelled sediment profiles with measured pore water data for the Santa Barbara Basin and the Iberian margin (compare Section 3.2). Results show that OMEN-SED is able to capture main features across a range of different environments without changing model parameters (e.g.

**Figure 6.** Pattern plot, showing the output sensitivity for each SWI flux (i.e. the chemical compounds on the vertical axis) and each input factor (i.e. the model parameters on the horizontal axis) for two idealised sediment cores. White patterns are assigned where the SWI flux is independent of the specific parameter.

**DH:** Rather low  $PO_4$  sensitivity - bc of Equil. concentr.?

930 stoichiometric ratios or secondary reaction parameters) to site specific conditions. For the two open Iberian margin stations (108 and 2213 m) OMEN-SED fits all observations well. OMEN-SED does especially well at depth 2213 m by reproducing the deep  $O_2$  penetration and the subsurface maximum in  $NO_3$  concentration due to the nitrification of  $NH_4$ . For the anoxic Santa Barbara Basin (585 m) the decrease in  $SO_4$  and the increase in  $ALK$  concentration with sediment depth is well represented, indicating the importance of sulfate reduction as the primary pathway of OM degradation at this site (compare Meysman et al., 2003). However, a misfit is observed for  $H_2S$  and  $PO_4$  in the upper 20 cm of this sediment core. The discrepancy for  $H_2S$  can be explained by high iron(III) hydroxide concentrations, which is reduced to degrade organic matter (especially in the 2 – 4 cm depth interval), therefore placing the beginning of the sulfate reduction zone and the production of 935  $H_2S$  to the deeper sediments (Reimers et al., 1996). In addition, produced dissolved Fe reacts with  $H_2S$  to form iron sulfides (e.g. pyrite,  $FeS_2$ ) and thus further inhibits the rise of  $H_2S$  (Reimers et al., 1990). The iron cycle also plays a critical role for phosphorus, as the reduction of iron(III) hydroxides in the surface sediments releases sorbed phosphate, leading to pore waters around and below 2

**Figure 7.** Coloured scatter plots ( $k_1$  vs  $f_1$ ) of resulting OMEN-SED SWI-fluxes for the 400m anoxic (A:  $\text{NO}_3^-$ ) and 4000m oxic (B:  $\text{O}_2$ , C:  $\text{NO}_3^-$ ) scenario. Negative values representing a flux from the water column into the sediments. Indicated area in red at the respective colour scale represents the range of benthic fluxes in the global database of Bohlen et al. (2012).

**DH:** Why mainly negative  $\text{NO}_3$ -flux 4000m in contrast to database!?... might change when using diff. gamma

cm which are supersaturated with respect to fluorapatite, thus initiating CFA precipitation. Reimers  
 945 et al. (1996) could even show that the accumulation of CFA is mainly restricted to the near-surface sediments ( $\sim 5$  cm) instead of throughout the sediment column. As OMEN-SED does not include an iron-cycle, and Fe-bound P and CFA processes are highly parameterised, the model is not able to capture these complex, non-steady state phosphorus dynamics at this specific site. For the Nazaré Canyon station (4298 m) satisfactory fits could be realised apart from  $\text{NH}_4$ . However, also Epping  
 950 et al. (2002) could not obtain a better fit using a more complex diagenetic model. They suggested non-local solute exchange resulting from bioirrigation being responsible for the higher  $\text{NH}_4$  concentrations at this site which is neglected in their model, as well as in OMEN-SED. Furthermore, the fractured POC profile (indicating episodic depositional events through the canyon) could have been approximated using a different partitioning of the bulk POC into labile and refractory pool with  
 955 different degradation rate constants. Thus, leading to a better fit of the  $\text{NH}_4$  profile. In general, better

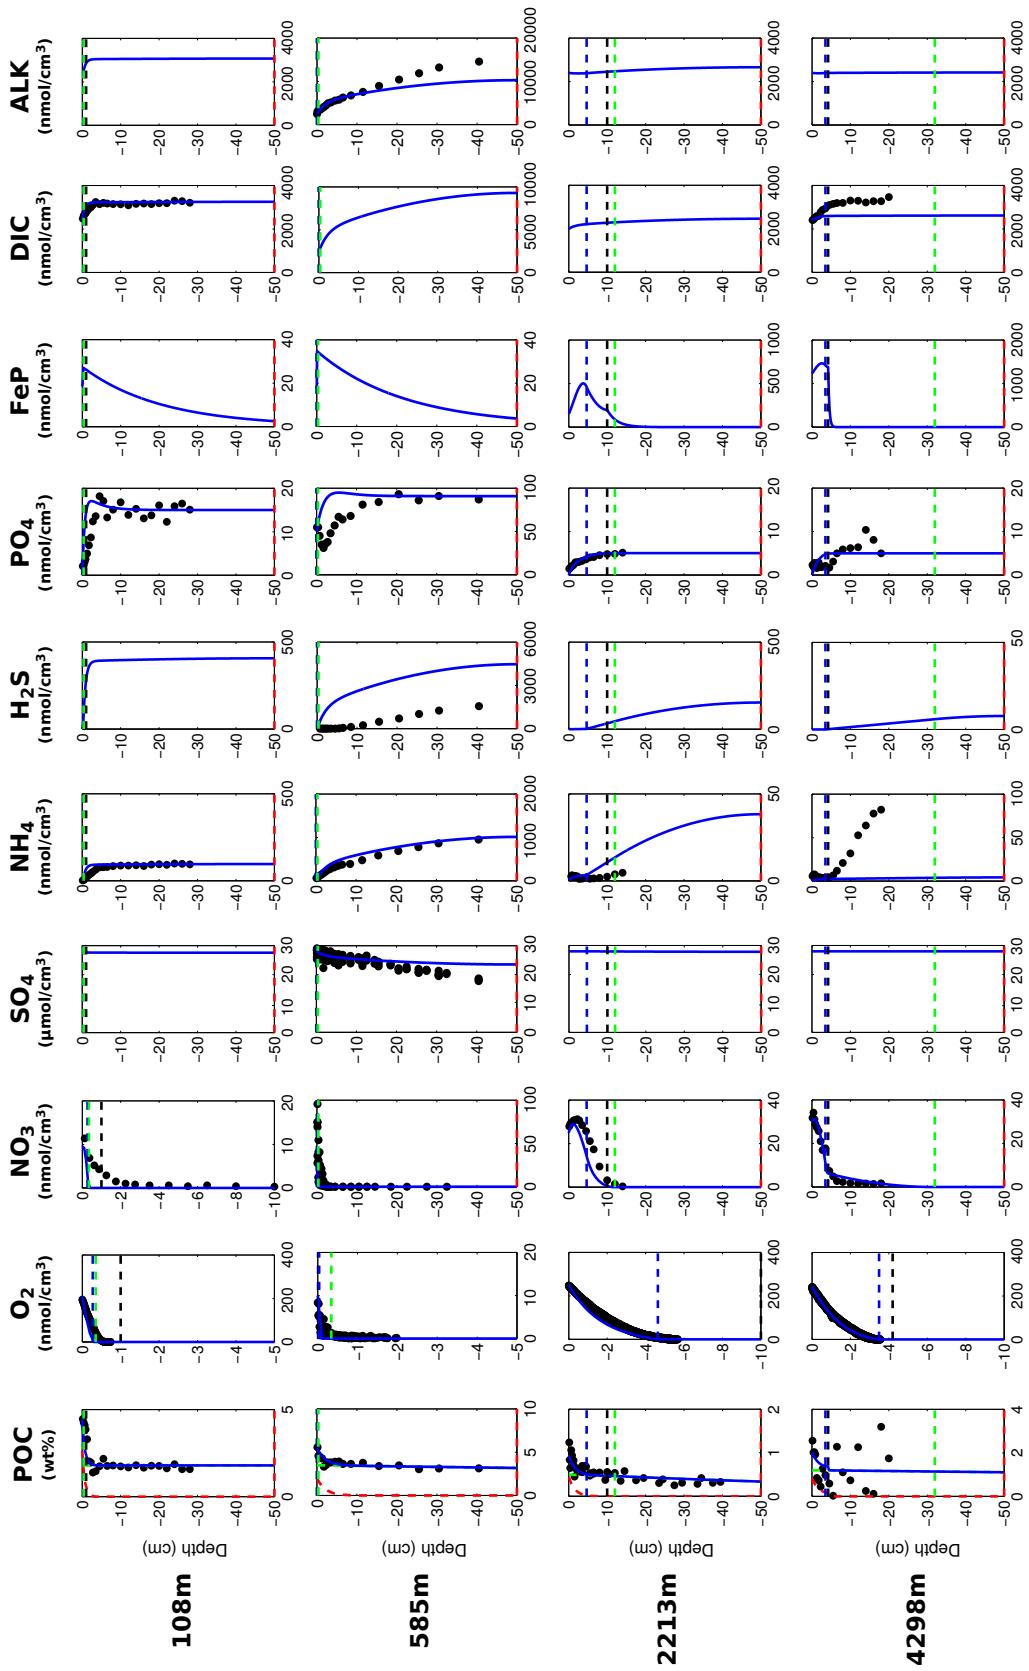

approximations of the data could have potentially been acquired by applying a sensitivity study using different NC-ratios (e.g. Epping et al., 2002, report different ratios from Redfield stoichiometry) and exploring the parameter space for the secondary reaction parameters ( $\gamma_{NH_4}$ ,  $\gamma_{H_2S}$ ). However, considering these generalisations and our assumption of steady-state, which might not be valid, particularly for the complex Santa Barbara basin, the shallow core and the Nazaré Canyon, which are affected by seasonality and biology, OMEN-SED performs well in capturing the main dynamics.

## 5.2 Stand-alone simulations of global ocean transect

Figure 9 compares simulated SWI-fluxes of TEAs (i.e. O<sub>2</sub>, NO<sub>3</sub> and SO<sub>4</sub>) along the global hypsometry using OMEN-SED (black lines) with the results of Thullner et al. (2009) (red lines). Observations for O<sub>2</sub> and NO<sub>3</sub> fluxes are taken from Middelburg et al. (1996). Also plotted in Fig. 9A are the total oxygen uptake (TOU) estimates presented in Thullner et al. (2009) (filled red symbols), who assumed the organic matter flux to be equivalent to TOU. Due to the applied empirical relations organic matter flux to the seafloor decreases by 2 orders of magnitude from 100 to 5000 m and its degradation rate constant by 1 order of magnitude (Table 14). Therefore, the rate of organic matter degradation is about 50 times greater at 100 m than at 5000 m (compare Thullner et al., 2009), thus resulting in a decrease of TEA-fluxes along the hypsometry (Figure 9). The 95%-reoxidation experiments (●, in Fig. 9) show proportionally higher O<sub>2</sub> in-fluxes as the 5%-reoxidation experiments (▼) because more O<sub>2</sub> is utilised for in situ production of NO<sub>3</sub> and SO<sub>4</sub> in the sediments. This is also mirrored by the increased NO<sub>3</sub> out-flux and decreased SO<sub>4</sub> in-flux for shallower SFDs. This is in line with results of Thullner et al. (2009) who could show that in situ production is an important source for SO<sub>4</sub> and is responsible for ~80% of the total OM degradation rate at depths between 100 and 2000 m (SO<sub>4</sub> is not used for OM degradation in OMEN-SED below 2000m). In general, Figure 9 shows that OMEN-SED captures the main trends in observed TEA fluxes well and fluxes calculated with BRNS fall within the range of possible OMEN-SED results.

In particular, the observed O<sub>2</sub> fluxes in the upper 2000m are well predicted by the two OMEN-SED simulations. Oxygen fluxes for the deep-sea sediments, however, are slightly underestimated. These deviations can presumably be related to the assumed 1-G description of organic matter degradation, which neglects the more labile OM pool. This highly reactive pool is degraded close to the sediment surface, thus promoting higher aerobic degradation rates and higher O<sub>2</sub> fluxes. Nitrate fluxes in the upper 500m of the Atlantic Ocean are well predicted. However, as in Middelburg et al. (1996) the direction of calculated nitrate fluxes in the upper 1000m of the Pacific Ocean differ from the observations. Middelburg et al. (1996) related these discrepancies to the globally averaged model parameters and the applied boundary conditions. They could reduce the disagreements significantly by using more representative bottom water concentrations for the eastern Pacific and a higher flux of labile organic matter for their 2-G model. By changing the boundary conditions and the NC-atomic ratio of organic matter for the whole hypsometry, it is possible to obtain a better model-data fit with

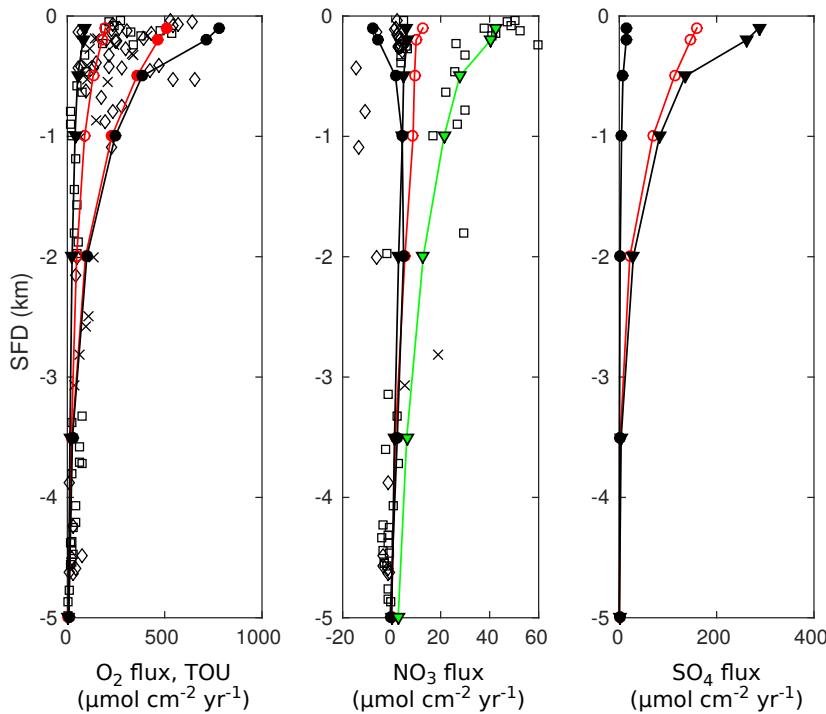

**DH:** Not sure, if this 80% is correct (seems to be pretty high)... but that's how I understand Thullner et al. (2009) - see pg. 12 for 80%!

**Figure 8.** Modelled (curves) and measured (filled dots) dissolved and solid phase pore water profiles for four different sediment cores. Note that different scales are used for different stations. The blue POC curve represents the sum of the refractory (green) and labile (red) POC fraction.

OMEN-SED for the shallow Pacific Ocean (green line in Fig. 9B). Following Bohlen et al. (2012), who could show that the atomic NC-ratio strongly deviates from Redfield stoichiometry (0.151) with specifically lower values for the East Pacific Ocean, we adopt their globally averaged value of 0.067.

995 In addition, bottom water conditions are changed to low oxygen/high nitrate levels more likely to be found in the shallow Pacific Ocean ( $O_2 = 10$  nanomole  $\text{cm}^{-3}$  and  $\text{NO}_3 = 80$  nanomole  $\text{cm}^{-3}$ ).

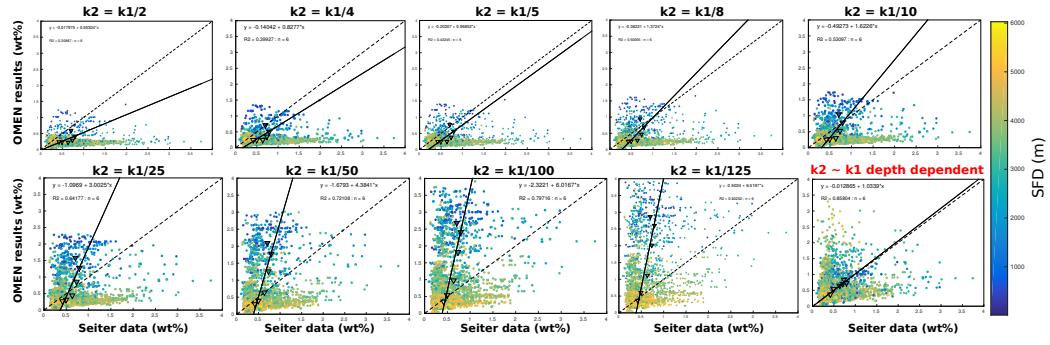

**Figure 9.** Fluxes of  $O_2$ ,  $\text{NO}_3$  and  $\text{SO}_4$  to the sediment along the global hypsometry. Red lines (with open symbols) are modelled fluxes from Thullner et al. (2009) using BRNS; black lines are results from OMEN-SED ( $\bullet$  :  $\gamma_{NH_4} = \gamma_{H_2S} = 0.95$ ;  $\blacktriangledown$ :  $\gamma_{NH_4} = \gamma_{H_2S} = 0.05$ ). Observations of TEA fluxes are taken from Middelburg et al. (1996) ( $\diamond$ : Atlantic,  $\square$ : Pacific,  $\times$ : Arctic/Indian Ocean). Also plotted in Figure (A) are the total oxygen uptake (TOU) estimates of Thullner et al. (2009) (filled red symbols). The green line indicates OMEN-SED results for low oxygen/high nitrate levels and the lower NC-ratio. Negative values are directed out of the sediments.

### 5.3 Coupled pre-industrial simulations

OMEN-SED has been coupled to the global Earth system model cGENIE as described in Section ??.

1000 Describe Figure 13 and compare with what we know. E.g. Thullner et al. 2009!

**Figure 10.** TEXT TEXT TEXT TEXT

Schulz and Zabel: The basic mechanism inducing microbial activity is the supply of organic matter to the seafloor and this is generally coupled to surface water productivity. Most of the highly productive areas in the global ocean are adjacent to the continents, so that we can expect a decrease 1005 of degradation intensity from the coastal marine environments over the continental shelves and slopes into the deep-sea. This becomes evident when we look at the data compiled by Middelburg et al. (1993) which indicate that 83% mineralization and 87% burial in marine sediments occurs in the coastal zone occupying only 9% of the total ocean area. This means that the sediments with the highest respiration rates also have the highest burial efficiency in marine environments. Fluxes 1010 of oxygen and nitrate, therefore, vary over several orders of magnitude between oligotrophic open ocean areas and continental shelf and slope areas. This is about 50 to 6,000 mmol m<sup>-2</sup> yr<sup>-1</sup> for oxygen and -600 to 380 mmol m<sup>-2</sup> yr<sup>-1</sup> for nitrate ...

(SHOW O<sub>2</sub>, NO<sub>3</sub> AND E.G. PO<sub>4</sub> SWI-fluxes).

Could also plot Figure 4 from Palastanga et al. (2011) with POC wt% for different sites in the 1015 ocean! UNITS of Fe-P! This is a solid! Therefore not nmol/cm<sup>3</sup> rather mol/g as in Palastanga...

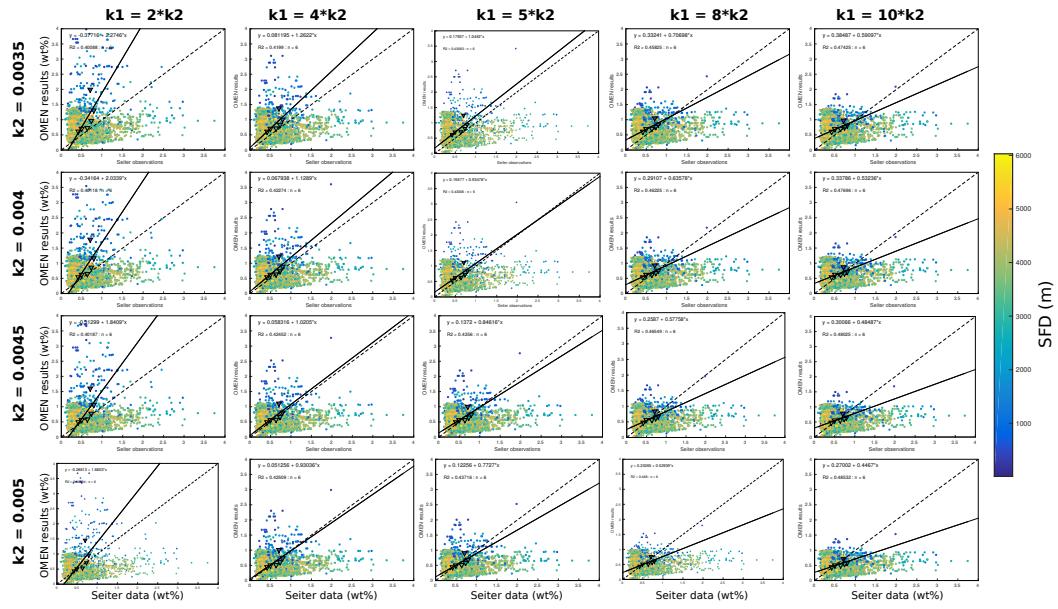

Also check what water column features to show and maybe sediment P or Fe-P concentrations (see PALASTANGA et al. 2011, 2013).

Stolpovsky: bioturbated sediments deposited at continental margins quickly become anoxic within 1020 a few millimeters [Wenzhöfer and Glud, 2002].

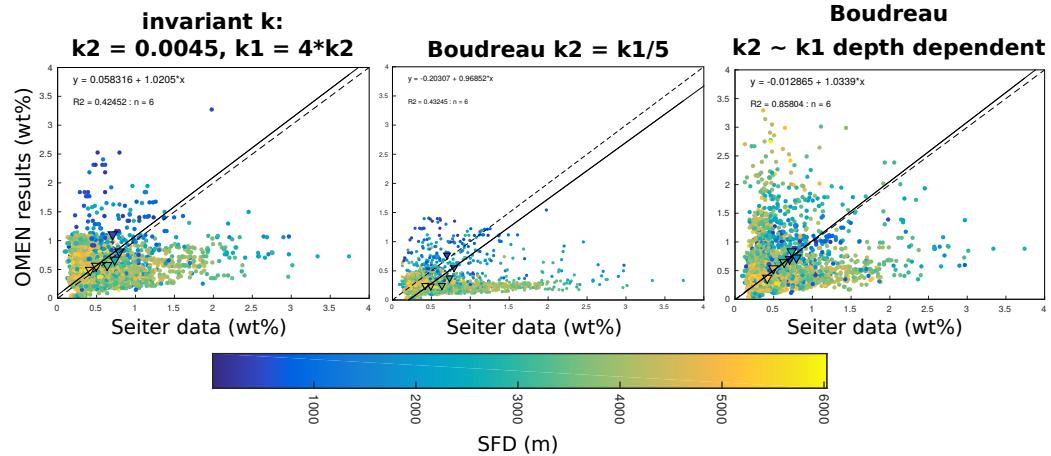

**up until here**

## 6 Scope of applicability and model limitations

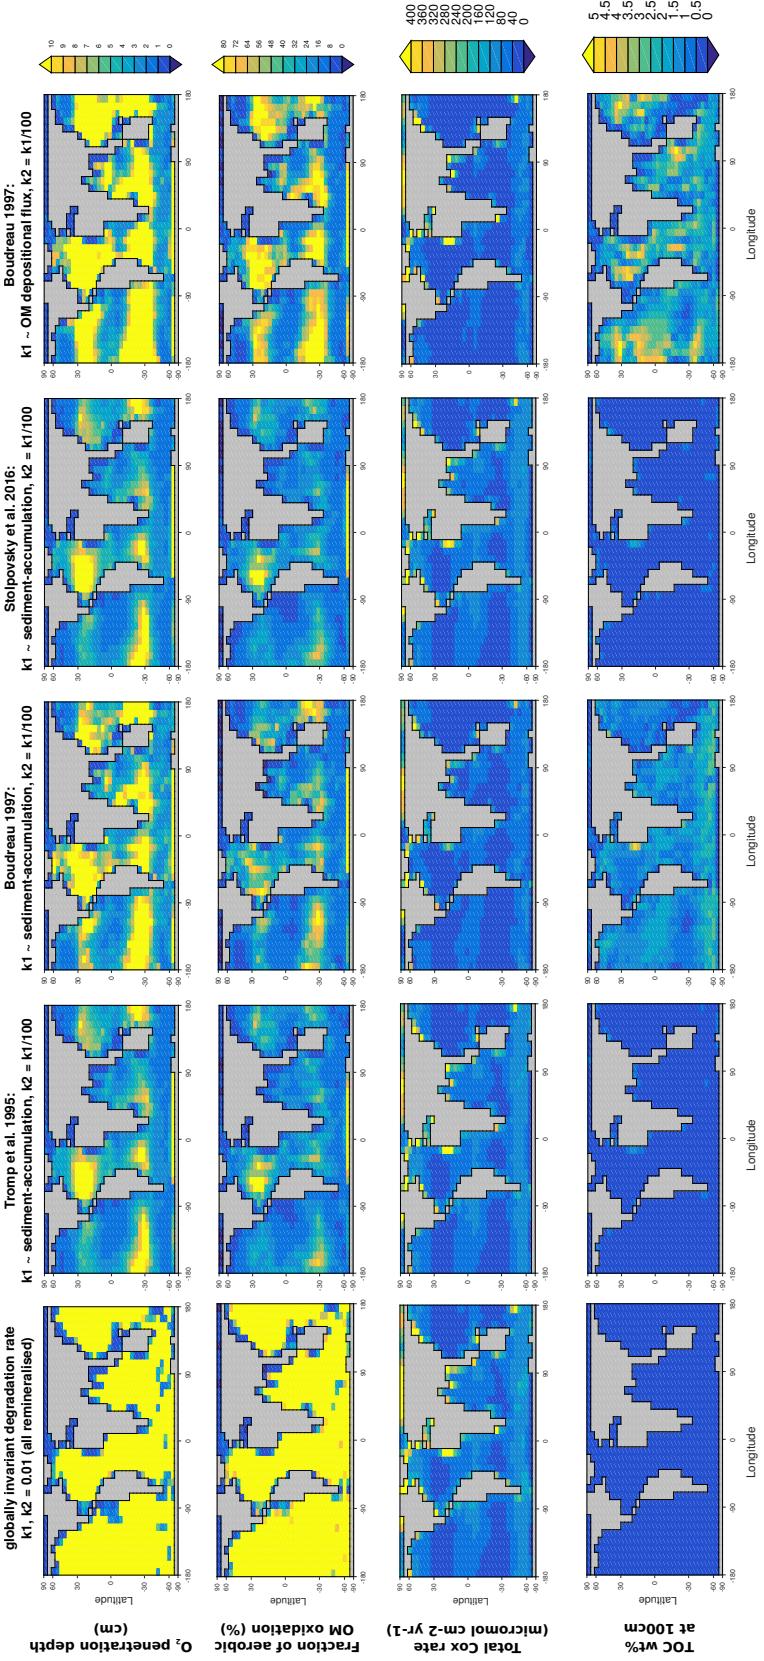

State-of-the art numerical models representing the full complexity of the diagenetic processes typically perform adequately at reproducing site-specific biogeochemical dynamics, however, tuning 1025 model parameters is laborious, the computational demand is high and, thus, their transferability to

**Figure 11.** TEXT TEXT TEXT TEXT

**Figure 12.** TEXT TEXT TEXT TEXT

**Figure 13.** Results of OMEN-cGENIE coupling using different, published parameterisations for the OM degradation rates ( $k_1$ ,  $k_2$ , compare Table ??) coupled to the same cGENIE ocean setup. All results shown are sediment characteristics calculated by OMEN-SED. **NOTE:** Preliminary results (here  $\text{frac2}$  still constant!) **TODO:** plot wt% just until 3%.

the global scale is limited. On the other hand, analytical models are very efficient, but existing approaches coupled to global models generally use highly simplified reaction networks, often restricted to oxic degradation with a limited number of explicit pore water tracers. However, our ability to assess the role of organic matter dynamics for global biogeochemical cycles and climate requires  
1030 tools that resolve the most important biogeochemical processes and tracers explicitly, while at the same time are computationally efficient and have a degree of predictive capability to extrapolate knowledge to data poor areas. The new model OMEN-SED presented here is a legitimate compromise between complexity of biogeochemical processes and computational efficiency. Its scope of applicability covers the entire range from regional to global scales. OMEN-SED's computational  
1035 efficiency facilitates its use in two very different ways. Firstly, it can be coupled to global Earth system models and therefore allows the investigation of coupled global biogeochemical dynamics over different timescales. Secondly, it can be used to calculate quantitative sensitivity indices requiring large sample sizes such as variance- or density-based approaches. Therefore, OMEN-SED can help to quantitatively investigate how systematic variations in model parameters impact the model out-  
1040 put, for instance when the model has been tuned to a site-specific problem. Due to the represented anaerobic processes and secondary-redox reactions, OMEN-SED is also useful to investigate the role of benthic-pelagic coupling on the development of ocean anoxia and euxinia for instance during extreme climate events such as OAEs. On more regional scales it can be applied to systems like continental margins or estuaries which are characterised by complex interactions between different  
1045 pathways of organic matter degradation and redox reactions. Here, the model can help to disentangle the complex process interplay that drives the biogeochemical dynamics and give quantifications for upper and lower constraints of carbon and nutrient budgets for these dynamic systems. In addition, OMEN-SED can be used to model eutrophication processes in shallow coastal waters as sediment-water oxygen and nutrient exchange fluxes are explicitly modelled and depend on reoxidation of  
1050 reduced substances which causes a substantial part of oxygen consumption in these environments.

However, the model presented here, even more complete than previous analytical models, is still associated with a certain degree of simplifications. In order to solve the diagenetic equation analytically important assumptions have been made, which limit the general applicability of the model.  
1055 One of the most important simplifications is assuming steady-state. When coupled to an Earth system model this assumption is only valid if the relevant variability in boundary conditions and fluxes is generally longer than the characteristic timescales of the reaction-transport processes. In that case the sediment column can be described by a series of pseudo steady-states as it is done in OMEN-SED. Consequently, the model can be used for investigating the long term effects of changes in boundary conditions such as the the input of OM or bottom water oxidation state on degradation  
1060 and burial dynamics, as for instance during OAEs. Yet, it is not able to predict the system response to short-term or seasonal variations of boundary conditions. The separation of the sediment column into distinct biogeochemical zones and the resulting lack of overlap in degradation pathways may

cause distorted organic matter degradation rates for the different TEAs. For instance, in OMEN-SED denitrification does not occur in the oxic zone, while in reality, although inhibited by the presence of  
1065 oxygen, denitrification can still occur in the oxic zone, even at shallow sediments depths with high OM contents. Manganese and iron are not represented and as such OMEN-SED is not able to model all processes important in coastal marine environments and highly accumulating upwelling regions. This can cause problems when modelling H<sub>2</sub>S and PO<sub>4</sub> profiles in anoxic environments as their concentrations are affected by these metal ions (compare Section 5.1). In addition the depth invariant  
1070 porosity limits the correct calculation of the sediment-water interface flux of dissolved species as in reality porosity decreases with sediment depth.

## 7 Conclusions

In this paper we have described and tested a new, analytical early diagenetic model resolving organic matter cycling and associated biogeochemical dynamics called OMEN-SED. Our new model is the  
1075 first of this class of analytical approaches to explicitly represent oxic degradation, denitrification, sulfate reduction and implicitly methanogenesis, as well as the reoxidation of reduced substances produced during organic matter degradation. Pore water tracers include O<sub>2</sub>, NO<sub>3</sub>, NH<sub>4</sub>, SO<sub>4</sub>, H<sub>2</sub>S, DIC and ALK and the solid phase includes two fractions of organic matter, Fe-bound P and authigenic Ca-P minerals. We have shown that the new analytical model is able to reproduce observed  
1080 pore water profiles from different ocean depths when organic matter partitioning and degradation rate constants are tuned to site specific conditions. An extensive sensitive analysis, based on the novel density-based PAWN method (Pianosi and Wagener, 2015), has been performed to asses the importance of 11 internal model parameters for all resulting SWI-fluxes. The results reveal that the degradation rate constant for labile organic matter is the most influential parameter for all model  
1085 outputs. Under anoxic conditions secondary redox parameters exert an important control on related SWI-fluxes of SO<sub>4</sub>, H<sub>2</sub>S, NH<sub>4</sub> and alkalinity. In addition, the sensitivity analysis showed that globally observed benthic O<sub>2</sub> and NO<sub>3</sub> fluxes fall well into the range of produced model results.

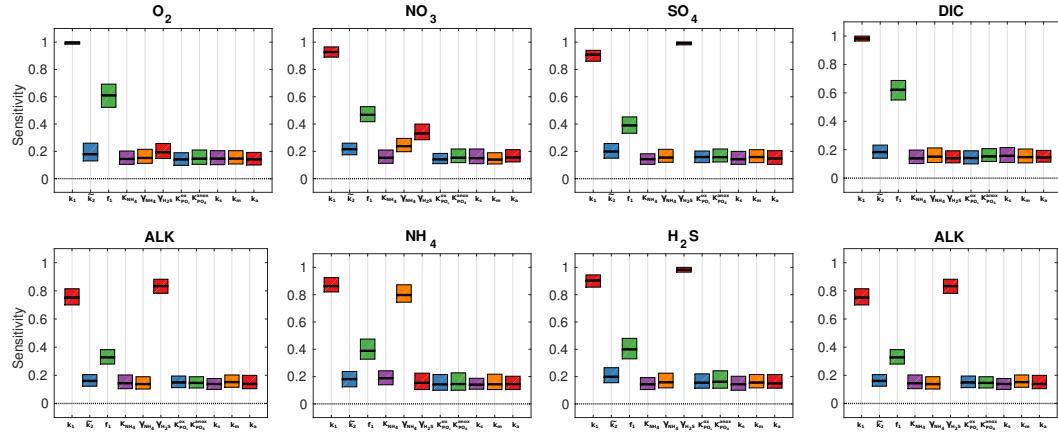

Furthermore, the coupling of OMEN-SED to the Earth system model cGENIE is described and various published parameterisations for the apparent first order degradation rate constant are tested  
1090 to fit the model to observed global organic matter concentrations. **TODO: write about results.** ...in order to investigate the role of sediments for global biogeochemical cycles and climate.

## 8 Code Availability

The OMEN-SED source code (Fortran and Matlab) related to this article is provided as a supplementary package together with a ReadMe file, where hardware and software requirements, source  
1095 code files and model output file management are fully described.

## Appendix A: Reaction Network

## Appendix B: Sensitivity Analysis

**Figure 14.** Move to Appendix Box plot of parameter sensitivities for the calculated SWI-fluxes for the 4000m oxic condition. Average sensitivities (black lines) and 90% confidence intervals using  $N = 11200$  model evaluations and  $N_{boot} = 100$  bootstrap resamples.
